The papers presented at the section on secondary agricultural education differ materially from those presented at the first section, in that only one of the 11 papers discusses the work of a particular institution (the Provincial School of Agriculture, Barcelona, Spain). The other papers are taken up with discussions of the educational value of secondary courses in agriculture, desirable features of such courses, qualifications of teachers, agricultural schools for women, etc.

At the section on popular education 20 papers were presented. These discuss such topics as traveling schools, agricultural instruction in primary schools, courses for farmers, courses in agriculture for soldiers, and the service of agronomes. The papers presented at the fourth section are devoted to the discussion of reading circles, agricultural libraries, agricultural journals, lantern slides, lectures, and other means of disseminating information.

Volume 2 of the report is taken up with the proceedings of the congress.

**What a university farm is for**, L. H. BAILEY (*California Sta. Circ. 15*, pp. 4).—An excerpt from an address previously referred to editorially in this journal (*E. S. R.*, 17, p. 216).

**The prospect for education in horticulture**, L. H. BAILEY (*Reprinted from West. N. Y. Hort. Soc. Proc.*, 51 (1906), pp. 7).—A paper presented before the Society at its annual meeting in January, and published as a separate from the proceedings.

The author holds that at present our colleges are trifling with the subject of horticulture and teaching those things that are easily demonstrable rather than entering into the core of the matter. The college department of horticulture should have at least three strong divisions—pomology, floriculture, and the nursery business. The laboratory work in each of these departments should cover the whole theory and process of the given art. The pomological division should be a laboratory of perhaps 50 acres of actual orchards, in which every phase of the work from start to finish might be in natural operation. Floriculture as well as the nursery business should be taught by men not only thoroughly grounded in the principles of these subjects, but skilled on the craft side as well.

The manufacturing side of horticulture, such as canning, preserving, and evaporating vegetables and fruits, making jellies, juices, and other secondary products, is not yet taught in any institution, and sooner or later must form a part of the instruction in the department of horticulture. The higher institutions of learning, it is held, should teach the trades, or teach in preparation for them, as well as the professions, providing, always, that the method be such as to educate broadly at the same time.

**Farmers' institutes** (*Ohio Sta. Circ. 44*, pp. 4).—A list of station officers and the subjects each is prepared to discuss at farmers' institutes.

**Why the friends of agricultural progress believe that agriculture should and will be taught in the public schools**, A. C. TRUE (*California Sta. Circ. 17*, pp. 14).—A paper read at the joint session of the California Teachers' Association and the State Farmers' Institute at the University of California, December 26-29, 1905.

The subject is discussed from two points of view: (1) The economic, social, and educational needs of agriculture and agricultural people as related to the present civilization, and (2) the pedagogical requirements of a school system which shall be adapted to the masses of people in a democratic and industrial State and to the symmetrical culture of the mind and body of the human child.

**Agriculture in the common schools**, J. H. BLUFORD (*South. Workman*, 35 (1906), No. 2, pp. 107-111).—An address delivered before the North Carolina Teachers' Association at Greensboro.

**Elementary agriculture**, A. B. GRAHAM (*Normal Instr. and Teachers' World*, 15 (1906), No. 4, pp. 9-11, figs. 5).—This is a plea for nature study and agriculture in the rural school. It includes a discussion of the nature of work to be undertaken, suggestions for correlating agricultural work with geography, arithmetic, language, drawing, and the social life of the pupils, and hints concerning the training of teachers for such work.

**Teaching of agriculture in public schools**, T. L. LYON (*Univ. [Nebr.] Jour.*, 2 (1906), No. 5, pp. 6, 7).—After commenting briefly on the lack of instruction in rural schools relating to the lives and occupations of the pupils, the writer gives two reasons why agriculture should be taught in high schools. "First, it contains the material with which to build a course of study second to none in educative and esthetic value; and, second, it may treat of a line of work vastly more practical and tangible than any other to the agricultural people of our State."

Instruction concerning soil and soil moisture is mentioned as of the greatest importance for Nebraska conditions, this to be followed by some attention to field crops, stock raising, dairying, and horticulture, keeping in mind that special emphasis should be given to those phases of agriculture most in vogue in the homes of the particular parts of the State in which the students live. Well-directed laboratory

work is mentioned as one of the means whereby school work may be freed "from its mechanical grind—its repetition of words and sentences without the thought content." General suggestions concerning the nature of laboratory work are given.

**The advisability of agricultural education in elementary schools,** L. H. BAILEY (*Agr. of Mass., 1904, pp. 93-120*).—This includes an address by L. H. Bailey, with discussion.

The first speaker, in giving reasons why young men leave the farm, suggested lack of business opportunity on the farm, ambition for large things, opportunity to work for others without financial risk, the attraction of more money, shorter hours, and social and intellectual entertainment in the city, and the influence of his early teaching. This last includes parental influence, that of the preacher, and that of the teacher. The farmer often deplores his own business, the preacher until quite recently has confined himself largely to the sphere of morals and religion, and the teacher, as a rule, has very little touch with rural affairs. She has been trained from the town and city point of view, and the books she uses employ not the problems of the farm, but the problems of the city. Suggestions for remedying some of the faults of teaching are pointed out and reasons given for teaching agriculture.

**Hints and helps for young gardeners,** H. D. HEMENWAY (*Hartford, Conn., 1906, pp. 59, figs. 17, dgm. 1*).—A guide for school and home gardeners intended for those who are young either in years or in experience.

Following an introductory chapter in which the value and influence of gardening are discussed, chapters on the following subjects are given: How to plan the garden, soil tillage, how to test seeds, how to plant, how to dig and set trees, how to make a hotbed and care for the same, strawberry culture, asparagus culture, and window gardening. The chapter on how to plant contains planting tables for vegetables and flowers in which is condensed much valuable information concerning the time, place, and manner of planting; how long it takes each plant to produce flowers and mature seed or to produce edible portions, and in the case of vegetables what part is eaten, how it is prepared for eating, and what the cultivation of each plant teaches.

**A course in nature study,** F. L. STEVENS and Mrs. F. L. STEVENS (*N. C. State Supt. Pub. Instr., Teachers' Bul. 5, pp. 32*).—An outline is given for nature-study work by months, extending through 7 grades of elementary school work. This is followed by suggestions for elaborating the nature-study outline, in which one lesson is treated in considerable detail.

It is recommended that during each month at least one lesson be conducted upon each of the following subjects: Plants, animals, soil, and sky. The object of the work, as stated in the introduction, is not primarily to give information or knowledge, but "to arouse an interest in nature; to put the pupil in a sympathetic attitude toward nature for the purpose of increasing the joy of living."

**How to teach the nature-study course,** J. DEARNESS (*Toronto: Copp, Clark Co., Ltd. [1905], pp. 206, pls. 5, figs. 41, dgm. 1*).—This is a text-book prepared to aid teachers in presenting that part of the prescribed school courses of Nova Scotia, Ontario, and Manitoba relating to nature study and school gardening. Nature study is first treated in a general way and then taken up with reference to the prescribed courses which are outlined by grades and subject-matter. A list of publications useful for study and reference is given.

**Nature study with common things,** M. H. CARTER (*New York, Cincinnati, Chicago: American Book Co., 1904, pp. 150, pls. 18*).—This is a laboratory guide of nature study treated from the viewpoint of elementary science. It is intended for pupils in fourth, fifth, or sixth years of city schools.

Studies of 17 common fruits and vegetables are presented, each to be examined in its entirety, in cross section, and in vertical section. There is a sameness of treatment throughout, and, in the author's own words, "many of the observations the pupil is called upon to make in these lessons bear upon no conclusion. They make no attempt to explain anything but are for the sole purpose of being made."

## MISCELLANEOUS.

**Experiment Station Work, XXXIII** (*U. S. Dept. Agr., Farmers' Bul. 244, pp. 32, figs. 6*).—This number contains articles on the following subjects: Handling seed corn; adaptation of seed corn; effect of root nodules on composition of crops; fumigation of nursery stock; cooking quality of potatoes; food value of cottage cheese, rice, peas, and bacon; methods of feeding poultry; extermination of cattle ticks; and covered yards for cows.

**The sanitation of a country house**, H. B. BASHORE (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1905, pp. VI+103; rev. in Nature [London], 73 (1906), No. 1897, p. 437*).—A short nontechnical treatise on the sanitation of the American country home.

**Farm hygiene**, P. REGNARD and P. PORTIER (*Hygiène de la Ferme. Paris: J. B. Baillière & Son, 1906, pp. 477, figs. 168; rev. in Mois Sci., 8 (1906), No. 3, p. 7*).—One of the volumes of *Encyclopédie agricole* published by G. Wery.

**Accessions to the Department Library, 1905** (*U. S. Dept. Agr., Library Bul. 58, pp. 64*).

## NOTES.

---

**Connecticut Storrs Station.**—C. D. Jarvis, a graduate of the Ontario Agricultural College and of the University of Toronto, who has been pursuing advanced work at Cornell University, has been appointed assistant horticulturist to the station, and entered upon his duties early in June. H. D. Edmond, instructor in chemistry and physics in the college, has been appointed station chemist.

**Hawaii Station.**—A proclamation has been issued setting aside lands at Hamakua, Hawaii, for a tobacco farm. Experiments to cover three years are planned, which will be carried out under the direction of the Federal station. The funds for carrying on the farm are to be supplied by private parties.

**Louisiana Stations.**—Clifford Waldron, farm manager at the sugar station at Audubon Park, has resigned to accept a position in connection with an extensive sugar establishment in Antigua. He will be succeeded by A. E. Dodson. Dr. G. D. Harris, of Cornell University, has been elected to the chair of geology in the State University, and will divide his time between university duties and the direction of the geological survey of Louisiana.

**Maine University and Station.**—The "Maine Farming Special," run under the auspices of the college of agriculture and the experiment station over the Bangor and Aroostook Railroad, proved a great success. Thirty-one stops of two hours each were made, and eleven evening exhibitions were given. More than 20,000 people visited the train and listened to the addresses. A similar trip was run over the Maine Central Railroad in June.

The university is giving increasing attention to agricultural extension, and A. W. Gilbert, a graduate of the Massachusetts Agricultural College and of Cornell University, has been placed in charge of this work. Reading and correspondence courses on sixteen different topics are now offered. Efforts are being made to introduce instruction in agriculture and forestry into all of the normal schools of the State. It is now taught in the normal schools at Castine and Gorham, and it is planned to start the work in a small way next year at Fort Kent, Presque Isle, and Farmington. Small tree nurseries will be started at each of the normal schools. The university will offer at its summer school, July 2 to August 3, a course in nature study for teachers.

W. M. Munson has been relieved of his duties as professor of horticulture in the university, and will devote his whole time to experiment-station work. His title in the station has been changed to orchardist instead of horticulturist. L. H. Merrill, professor of biological chemistry, will hereafter give his entire time to the station as chemist. A. C. Whittier, assistant chemist at the Massachusetts station, has been appointed assistant chemist to the station, and Miss Joanna C. Colcord assistant chemist, in place of I. Nuremburg, resigned. Roydon Hammond succeeds Bessie G. Tower as seed analyst and photographer.

**New Jersey College and Stations.**—The legislature has appropriated \$24,000 for the establishment of short courses in agriculture, and \$6,500 for the maintenance of the same. The college also received \$27,000 due on scholarships for 1902-1905, and \$12,000 on scholarships for the present year. The station was given an appropriation of \$500 for the inspection of Paris green, and \$13,500 for work on the extermination of mosquitoes.

**Cornell University.**—The traveling summer school of agriculture has been postponed, the requisite number of students not having complied with the requirements.

**North Carolina College and Station.**—C. W. Burkett has resigned his position as professor of agriculture in the college and agriculturist in the station, and will have charge of short agricultural courses at Ohio State University.

C. B. Williams, who has been connected for a number of years with field-crop work of the test farms under the State department of agriculture, has been added to the station staff. Provision has been made for an additional worker in plant breeding and forage crops, for a tobacco specialist, and an assistant in plant diseases who will give his entire time to the investigation of this subject.

Franklin Sherman, jr., formerly entomologist in the State department of agriculture and the experiment station, who has been connected with the Ontario Agricultural College during the past year, has returned, and R. S. Woglum, who has been acting entomologist in his absence, will be retained as his assistant. R. H. Harper and O. L. Bagley, assistant chemists, have resigned, to take effect September 1, and W. A. Syme, a former graduate of the college, has been appointed in this position.

**Ohio Station.**—Because of the increasing administrative work of the station, the office of assistant director has been established, and L. H. Goddard, experimentalist, has been appointed to that position. W. F. Pate, formerly assistant chemist in the University of Illinois, and L. L. La Shell have been appointed assistant chemists, and C. H. Kyle assistant agronomist.

**Oklahoma Station.**—John Fields has resigned the directorship of the station, to take effect October 1. This step has been in contemplation for several months, and is to enable him to give attention to private interests.

**Oregon College and Station.**—Mrs. Clara H. Waldo, of Macleay, has succeeded William E. Yates as a member of the board, and Austin T. Buxton, of Hillsboro, has succeeded B. G. Leedy. C. I. Lewis has been appointed horticulturist in the station.

**South Dakota Station.**—Frank A. Norton, assistant chemist, has resigned and has become associated with a laboratory for canning at Aspinwall, Pa.

**Utah College and Station.**—Funds have been set aside for the completion of the unfinished wing of the cattle barns and for the erection of an additional greenhouse. R. W. Clark, professor of animal husbandry, has resigned to accept a position with the Montana College and Station, and J. T. Caine, a graduate of the college, has been appointed in his place. J. W. Bolte, poultry manager, has accepted a position at the Rhode Island Station. J. A. Crockett, instructor in dairying, has also resigned to engage in private business. E. D. Ball, entomologist, has been granted leave of absence for one year to pursue his studies.

**Vermont University and Station.**—The corner stone of Morrill Hall, the new agricultural building, was laid June 26. W. J. Morse, assistant professor of botany, has been appointed vegetable pathologist to the Maine Station and will enter upon his duties July 1.

**Virginia College and Station.**—D. O. Nourse, agronomist, retired at the close of the present college year, after many years of service, to engage in private business.

**Washington College.**—A four-year course in veterinary science has been established, leading to a bachelor's degree.

**Wisconsin University and Station.**—James Milward has been appointed assistant in horticulture, to take effect July 1. Leslie H. Adams, for many years farm superintendent at the college and station, has severed his connection with the institution.

According to a note in *Science*, plans for an agronomy building and an agricultural engineering building have been completed, and contracts for their erection are now being made. These contracts will provide for their completion before the beginning of the short course in agriculture next winter.

**Wyoming Station.**—R. E. Hyslop, a graduate of the University of Wisconsin and a postgraduate of the University of Missouri, has been appointed agronomist and will begin work July 1.

**Hampton Normal and Agricultural Institute.**—The Shellbanks Farm, which has hitherto been conducted almost entirely on a commercial basis, has recently been turned over to the agricultural department under the direction of Prof. E. C. Bishop, and will henceforth be utilized largely for the instruction of agricultural students. A special three-year course has been inaugurated for those who wish to take agriculture as their main work, and each boy who undertakes the course will put in seven hours of every school day in actual field work under the direction of an instructor, and will also receive two hours of theoretical agriculture and occasionally some night work.

**Policy of the Carnegie Foundation.**—The trustees of the Carnegie Foundation for the Advancement of Teaching have announced the policy of the foundation, through an article by Henry S. Pritchett in *Educational Review* for June, 1906. The question as to the admission of State institutions to the benefits of the foundation has been left to be decided at the annual meeting of the trustees in November next.

In this connection it is recognized that "from the standpoint of education there are serious objections to the recognition in a State like Wisconsin, for example, of a modest college and the omission of the great State university, which is the real center of high education. On the other hand, an important question of general public policy is involved when a private agency steps in between the State and an institution which the State has founded and controls. For nearly a half century the great State universities in the Central West have labored to establish the principle that higher education in their respective States is to be maintained by the State itself. This principle has been established, and these universities are soon to be in possession of the largest incomes which any institutions in America receive. The State may, therefore, fairly be expected to provide a retiring-pension system for its own professors."

The decision of this matter will be awaited with much interest, as it will affect a large proportion of the workers connected with the agricultural colleges and experiment stations of the country.

**The International Agricultural Institute.**—A recent number of *Revue Scientifique* states that in spite of pessimistic predictions the future of this Institute is assured, since the following countries have signified their intention to cooperate in its establishment: Italy, France, England, Russia, Germany, Austria-Hungary, United States, Japan, Belgium, Holland, Switzerland, Spain, Portugal, Denmark, Sweden, Greece, Luxemburg, Servia, Bulgaria, Egypt, Persia, Mexico, Equador, Uruguay, Nicaragua, Cuba, and San Salvador, and other powers have signified their intention of cooperating. It is expected that, in accordance with the wish of King Victor-Emmanuel, the new palace in Rome will be completed in 1907, and the following year the work of the Institute will commence.

**Agriculture at Cambridge University.**—The board of agricultural studies reports that the Worshipful Company of Drapers, to whom it is already indebted for the endowment of the chair of agriculture, has offered \$25,000 toward the buildings required by the agricultural department, on condition that an equal sum be raised by the end of the year. Pledges of \$5,000 each have already been received from four persons.

**Agricultural High School of Berlin.**—A chair of fishery and fish breeding has been established at the Agricultural High School of Berlin and will be occupied by Dr. P. Schiemenz, director of the Müggelsee Biological Station, which now becomes a department of the Agricultural High School.

**Agricultural Continuation School in Germany.**—The first agricultural continuation school in the Province of Brandenburg was opened at Jessern last November and continued until the end of March. Fourteen students were in attendance, and the high grades which they maintained in the examinations at the close of the term indicated that the experiment was entirely successful. The subjects taught were

chemistry, soils, fertilizers, and feeding. It is planned to supplement the winter courses by Sunday afternoon lectures during the summer months, and to keep some oversight of the students in their practical work at home. The school was opened at the request of sons of property owners in Jessern and Goyatz, who also bore the cost of instruction.

**School of Agriculture, Cedara, Natal.**—The Cedara School of Agriculture, which was opened to students in the spring of 1906, provides a 2-year practical course in which students spend about 4 days a week in practical work in the field and workshop, and the remainder of the time in the study of such subjects as forestry, horticulture, dairying, veterinary science, entomology, agricultural chemistry, mathematics, book-keeping, and surveying. The school is provided with a new building containing 2 stories and a basement, the latter devoted to laboratories, kitchen, etc., the first floor to dining hall, library, and offices, and the second floor to dormitories and a large lecture hall.

**Children's Corn and Cotton Contest in Georgia.**—The Georgia State College of Agriculture and Mechanic Arts has arranged for children's contests in growing corn and cotton during the summer of 1906. These contests are open to schools or to pupils growing corn or cotton at home. County exhibits of the crops grown will be held during the month of October prior to the State Fair, and the contestants winning prizes in the county contests will be allowed to send their exhibits to the State Fair to enter competition for State prizes.

**Irish Training School of Domestic Economy.**—The Department of Agriculture and Technical Instruction for Ireland announces that in July, 1906, it will award 10 open scholarships and 10 limited scholarships to assist domestic economy students at the Irish Training School of Domestic Economy, Dublin. These scholarships will entitle the holders to free admission to the full course of training for teachers of subjects in domestic economy. Arrangements have also been made by the Department for the reception of a small number of students at St. Mary's Convent of Mercy, Portumna, to pursue studies in dairying, poultry keeping, horticulture, household management, cookery, laundering, etc.

**Monthly Weather Review.**—The editor of the *Review*, Prof. Cleveland Abbe, U. S. Weather Bureau, invites librarians of agricultural institutions to inform him promptly as to what numbers or volumes of the *Review* are needed to complete their sets of this periodical. He will be glad to supply the necessary numbers and volumes as far as possible.

**Miscellaneous.**—A bill appropriating \$80,000 to St. Lawrence University for the establishment of an agricultural course and \$12,000 for maintenance has been passed by the New York legislature and signed by the governor.

According to *Mark Lane Express*, the establishment of an agricultural college for Devon (England) is being considered under the Seale Hayne bequest.

Hon. W. T. Harris, commissioner of education, has resigned, and Dr. E. E. Brown, professor of the theory and practice of education in the University of California, has been appointed his successor.

Director M. A. Scovell, of Kentucky received the degree of doctor of philosophy from the University of Illinois at commencement.

Dr. W. C. Sturgis, formerly botanist at the Connecticut State Station, has been appointed dean of the new school of forestry, established in connection with Colorado College, to which reference has previously been made (E. S. R., 17, p. 722).

H. D. Hemenway, for a number of years director of the School of Horticulture, Hartford, Conn., has severed his connection with that institution and during the summer will conduct a course in nature study for teachers in the Woodland Farm Camp School, at Westchester, Conn.

# EXPERIMENT STATION RECORD.

VOL. XVII.

JULY, 1906.

No. 11.

---

The friends of agriculture will learn with sincere regret of the death of Hon. H. C. Adams, of Wisconsin, which occurred at Chicago, July 9, 1906.

Mr. Adams had shown himself to be a most earnest and intelligent friend of agricultural progress, whose varied interests had for many years received his active cooperation and support. As a member of the committee on agriculture of the House of Representatives, he brought to his work wide familiarity with the conditions and needs of agriculture, and judgment as to the means of accomplishing the desired ends, which made him an extremely useful man to the country at large. He was liberal and broad-minded in his conceptions, and active and aggressive in urging what he conceived to be for the common good. Although he took a prominent part in all matters relating to agriculture during his period of service in Congress, his success in securing the passage of the act for the further endowment of agricultural experiment stations stands out as a conspicuous feature of his public career, and has made him a National figure. This act placed him among the great benefactors of agriculture, along with Morrill and Hatch, and will serve as an enduring monument to his memory.

Mr. Adams' avowed intention when elected to Congress was to secure an increase of the appropriation for agricultural experiment stations. In this effort he showed not only an intelligent appreciation of the stations' work, but of the higher work in agricultural science, which must needs be quite limited under existing appropriations. Although not a student of science, he had become thoroughly imbued with the important relations of science in the development of agriculture, and he entertained high ideals for work on the frontiers of agricultural science.

The successful passage of the act which bears his name, after several years of labor in its behalf, was a matter of great satisfaction to him, and he took a keen interest in the preparations for its use. He was called just as the stations were coming into the realization of its benefits and before work under it had fairly been instituted. In the death of Mr. Adams the Federal Department of Agriculture, the experiment stations, and agricultural progress as a whole lose a strong and efficient advocate and supporter.

The appropriation for the U. S. Department of Agriculture for the fiscal year 1907 nearly reaches the ten million mark. The regular appropriation amounts to \$9,560,440, and to this is added emergency appropriations aggregating \$372,500. The grand total, \$9,932,940, represents an increase of \$3,050,250 over last year.

A large proportion of this increase is, of course, due to the funds provided for carrying into effect the new meat inspection law, but apart from this the appropriation is larger than last year by over \$900,000. Most of the changes came independently of the Department and as the result of popular demand, the emergency appropriations and a considerable number of other items being urged by outside interests. As a matter of fact, the total appropriation, excluding the increased amount for meat inspection, exceeds the estimates of the Secretary of Agriculture by \$156,730.

The act embodies an unusual number of new features, several of which are of interest as inaugurating new policies. It marks a growth of confidence in agricultural work and in the Department, and voices an increasing sentiment for Governmental supervision of certain large undertakings, administrative and otherwise, which affect the whole country and are not at present provided for by local agencies.

The Bureau of Animal Industry now leads all other branches of the Department in the amount of its appropriations—\$3,946,980. This figure does not include an emergency appropriation of \$82,500 for experimental work looking to the eradication of Texas fever ticks, which is to be carried on in cooperation with State authorities. The chief interest in the appropriation for this bureau naturally centers around the new meat inspection law, concerning which there has been so much discussion in the public press. The execution of this law will call for material expansion of the bureau's work in this direction. For this the new law makes a permanent annual appropriation of \$3,000,000. Although no specific amount has been mentioned for meat inspection in previous appropriations, about \$850,000 a year has been expended, so that the net increase for this purpose is about \$2,150,000.

Among other new duties the Bureau is authorized to make tests of tuberculin serums, antitoxins, etc., of domestic and foreign manufac-

ture, which are sold in the United States for the detection, prevention, treatment, or curing of diseases of domestic animals; and is also given \$5,000 to conduct experiments in the diseases prevalent among domestic animals in Minnesota and adjoining States, in cooperation with the Minnesota Experiment Station, with a view to developing antitoxin or preventive vaccines. Twenty thousand dollars is specially designated for "further developing the dairy industry of the Southern States, by conducting experiments, holding institutes and giving object lessons, in cooperation with individual dairymen and State experiment stations."

The amount appropriated for the Weather Bureau is \$1,439,240, an increase of \$46,250. The work provided for does not involve any particularly new features.

The largest increase, except in the case of the Bureau of Animal Industry, is for the Bureau of Plant Industry, \$142,860, making the total \$919,740. To this should be added an emergency appropriation of \$105,000 for continuing work against the cotton-boll weevil by encouraging the diversification of crops and improved cultural methods, breeding new cotton, etc. Some of the new features provided for in this Bureau are the provision for inspection of grain at certain points of export, for which \$15,000 is named, a special investigation of parasites and orchard diseases prevalent in the Ozark Mountain region, with a special appropriation of \$5,000, the erection of a laboratory and office building at the plant introduction garden at Chico, California, and \$3,500 for the improvement and macadamizing of gravel roadways in the Department grounds. The provision for the purchase of seeds for Congressional distribution, which was eliminated by the House of Representatives but was restored in the Senate Committee on Agriculture, remains \$242,920, of which as formerly \$37,780 is for the introduction of seeds and plants from foreign countries.

The Forest Service is given a round million, which is an increase of \$124,860 over last year. Under the emergency appropriations \$15,000 is provided for the erection of a wire fence on the Wichita Forest and Game Preserve, to provide a range for the buffalo herd presented by the New York Zoological Society; and \$2,500 for a building on Dismal River Forest Reserve in Nebraska. A new and important feature affecting the policy of the Government with reference to the forest reserves is incorporated in the act. This authorizes the payment each year of 10 per cent of the money received from these reserves to the State or Territory in which the reserves are respectively located, to be expended by the legislature for the benefit of the public schools and public roads of the county or counties in which the reserves are situated. This provision is looked upon with much favor, as it will in large measure offset the loss to the counties due to the withdrawal of land from settlement and ultimate taxation.

Under the present method of administering the forest reserves they

have become a considerable source of revenue. During the past fiscal year the proceeds from these reserves amounted to \$767,219.96. Of this amount \$203,443.27 was derived from sales of timber, \$39,224.96 from "trespass," on account of timber previously cut but not paid for, and \$514,086.74 for grazing. It is confidently expected that in a few years these reserves will not only be self-sustaining but will return a considerable revenue over their cost of management.

The total for the Office of Experiment Stations, including the \$720,000 for the State experiment stations under the Hatch Act, is \$974,860. The general maintenance fund of the Office is increased to \$25,500, aside from the statutory salaries. The special appropriation of \$3,000 for Alaska, for the purchase and introduction of live stock for experimental purposes, is continued, and the Hawaii Station is given \$5,000 additional to provide a suitable water supply. There is an increase of \$48,000 for irrigation and drainage investigations, making the total for that purpose \$122,200, and the field of the Office is broadened to include agricultural education, the act authorizing the promotion of elementary education in agricultural schools.

The total appropriation for the Office, aside from the amount carried for the State stations, is \$254,860, an increase of \$56,960 over last year. A clause in the act authorizes the Secretary of Agriculture to turn over to the Georgia Station the buildings and machinery at Waycross, Ga., which were used by the Department in the study of the production of table sirup, the condition being that the Georgia Station shall establish and maintain a substation at Waycross in the interest of the sirup and other agricultural industries in that part of the State.

In reality the act authorized the expenditure of \$240,000 which does not appear in any of the totals. This was on account of the Adams Act, increasing the Federal appropriation for the State experiment stations. Under the opinion of the Comptroller, this act would not have gone into effect until the fiscal year 1907, but it was construed by the agricultural bill to appropriate \$5,000 to each State for the fiscal year ending June 30, 1906, and following this construction the Treasury Department made these advances as soon as possible after the passage of the agricultural bill. This amounted to \$240,000 in all, a part of which will doubtless remain unexpended, owing to the late date in the fiscal year on which the bill passed. A considerable proportion of the stations, however, were enabled to secure necessary permanent equipment and the like for investigation to be undertaken with the new act, and the work will thus be started on a larger and more effective scale than would otherwise be possible, especially as the amount for the present year is increased to \$7,000.

For the Bureau of Chemistry the appropriation is \$174,180, an increase of \$19,180 over last year. The Bureau of Entomology receives \$94,610, an increase of \$10,140, of which \$5,000 is for investi-

gating the white fly affecting the orange groves of Florida. It also has an emergency appropriation of \$85,000 for its cotton-boll weevil investigation, and of \$82,500 for establishing a quarantine against the further spread of the gypsy and brown-tail moths in New England, in cooperation with the authorities in the different States concerned. The fund for the Bureau of Soils is increased \$16,800, making the total for this year \$221,460; that for the Bureau of Statistics amounts to \$210,560; and for the Biological Survey \$52,000, the same as last year.

The Office of Public Roads receives \$70,000, an increase of \$20,000, and the Division of Publications \$248,520, including, as usual, \$98,750 for the preparation and printing of Farmers' Bulletins. Other items are: Office of the Secretary, \$113,200; Library, \$25,880, an increase of nearly \$5,000; Division of Accounts and Disbursements \$32,210, and contingent expenses, \$37,000.

The new allotment to the Department from the printing fund is \$300,000 instead of \$185,000 as formerly. This increase is apparent rather than real, as the \$115,000 added is intended to compensate for certain changes in the printing law which place a large share of the expenses for the Yearbook, annual reports, and the like upon the Department. This fund, together with the proceeds from the forest reserves, which are available for the use of the Forest Service and are to be taken into account in future estimates, makes the total income of the Department for the fiscal year 1907 over eleven million dollars.

The growth of the Department in police or inspection duties is one of the most salient features of the development of the past year. The largest of these undertakings at present is the inspection of meats and packing houses. The agitation for more thorough control of the packing industry, with representations as to the inadequacy of the laws in force and the insufficiency of the appropriations for carrying them into effect, resulted in the passage of a law which is said by experts to be the broadest and most stringent of its kind in force in any country. Rarely has the weight of public sentiment been more forcibly felt in legislation than in the case of this law.

The law provides for ante-mortem and post-mortem examination of animals intended for meat, and of the products at various stages, all parts found to be "unsound, unhealthy, unwholesome and otherwise unfit for human food" to be destroyed for food purposes in the presence of an inspector. The inspection is extended to canned and otherwise prepared meats, which are required to bear the label showing that they have been inspected and passed, the same as in the case of fresh meat. The law directs that all products shall be condemned which contain dyes, chemicals, preservatives, or ingredients injurious to health, except when packed for export to a foreign country with whose laws such treatment does not conflict.

An important provision is that for a sanitary inspection of the packing establishments themselves, authorizing the Department to prescribe the rules and regulations of sanitation under which they shall be maintained, and to withhold the inspection label from the products of establishments which do not meet these requirements. The inspection label is a requisite to shipment of meat or meat products from one State to another, or to a foreign country, so that transportation companies are made subject to the law; and the inspection also extends to live cattle, sheep, swine, and goats intended for export. Penalties for violating the provisions of the law are fixed at a fine not exceeding \$10,000 or imprisonment for not more than two years, or both. Heavy penalties are also provided for bribery of inspection officials, or the acceptance of a bribe. Farmers and retail butchers are exempted from the requirements of inspection.

Another important line of inspection work inaugurated by the last Congress is that in connection with the execution of the National pure food law. This law prohibits interstate commerce in foods which have been adulterated or misbranded, or which are unwholesome or contain preservatives or other additions making them injurious to health; and it also prohibits the manufacture or sale of such products in any Territory, the District of Columbia, or our insular possessions. It covers foods, condiments, beverages of all sorts, drugs, and medicines. Heavy penalties of fine or imprisonment, or both, are imposed for violations of the law, and condemned goods in process of transportation from one State to another, or to a foreign country, may be confiscated.

The Department of Agriculture is charged with the administration of the law, with the collaboration of the Treasury Department and the Department of Commerce and Labor. The burden of maintaining the inspection of food products under this law and of determining what constitutes adulteration, will fall upon the Bureau of Chemistry of this Department. No funds have yet been appropriated by Congress for carrying the law into effect, but considerable time will be required for drawing up regulations and making the necessary preliminary arrangements. Congress will be asked to make an immediately available appropriation when it convenes in December next. It is the expectation of the friends of the measure that it will very materially strengthen and supplement the efforts of the several States in stamping out the various forms of sophistication which have become so prevalent.

An important branch of inspection work for which only a beginning is provided by the appropriation act is the grain inspection. There was considerable agitation of this subject at the recent session of Congress, the contention being that provision should be made for an inspection by the Department of Agriculture of grain for export to

foreign countries, this inspection being for quality, condition, and grade, and to serve as the basis for an official certificate. The bulk of grain is now sold on the certificate of inspectors employed by boards of trade and similar agencies, and there is frequently a lack of uniformity in these certificates for similar lots. Questions arise as to the accuracy of the certificate and the condition and deterioration in transit, out of which dissatisfaction has grown which has affected our foreign trade.

The result of consideration of this matter was that the Secretary of Agriculture was authorized "to establish at such points of export as he may deem expedient, laboratories for the purpose of examining and reporting upon the nature, quality, and condition of any sample, parcel, or consignment of seed or grain." The amount named for this purpose was \$15,000, which will obviously provide only quite limited facilities for such inspection, but will afford a court of appeal in doubtful or disputed cases. This is doubtless one of the features which will grow in extent as its importance and usefulness are realized, and may ultimately assume considerable proportions.

It will thus be apparent that the Department is adding to its administrative and investigational functions extensive and important inspection work, which is broadened to include not only the special interests of the farmers but the people as a whole.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY.

**Introduction to the investigation of products important in agriculture,** C. BOHMER (*Anleitung zur Untersuchung landwirtschaftlich wichtiger Stoffe*. Berlin: Paul Parey, 1906, pp. VIII + 135).—This book is intended as a guide for students and teachers in agricultural-chemical laboratories.

The methods described are in the main those approved by the International Congress of Applied Chemistry and of the Association of German Agricultural Experiment Stations. The topics treated are mechanical analysis of soils; examination of commercial fertilizers, including methods of determining phosphoric acid, nitrogen, potash, and lime; examination of feeding stuffs; determination of the sugar content of beets; milk examination; chemical analysis of soils, including preparation of hydrochloric-acid solutions and their examination, fusion with alkaline carbonates and reduction by means of hydrofluoric-acid, and the determination of nitrogen; and preparation of solutions used in analysis.

**Equilibrium between some bases when they are present simultaneously with phosphoric acid,** A. QUARTAROLI (*Gaz. Chim. Ital.*, 35 (1905), II, pp. 290-304; *Staz. Sper. Agr. Ital.*, 38 (1905), No. 7-8, pp. 639-657; *abs. in Jour. Soc. Chem. Indus.*, 24 (1905), No. 23, p. 1229).—The author reports studies of the conditions of equilibrium in the following systems: (1)  $1\text{H}_3\text{PO}_4 + \frac{1}{2}\text{CaO}$  (or  $\text{BaO}$ ) +  $2\text{KOH}$  (or  $\text{NaOH}$ ); (2)  $1\text{H}_3\text{PO}_4 + \frac{1}{2}\text{CaO}$  (or  $\text{BaO}$ ) +  $1\text{NaOH}$ ; (3)  $1\text{H}_3\text{PO}_4 + \frac{1}{2}\text{MgO} + 2\text{NaOH}$  (or  $\text{KOH}$ ); (4)  $1\text{H}_3\text{PO}_4 + \frac{1}{2}\text{MgO} + 1\text{NaOH}$  (or  $\text{KOH}$ ).

In the experiments which are reported 25 cc. of a normal solution of phosphoric acid was mixed with corresponding amounts of the alkaline solutions and the whole made up to 500 cc. An aliquot of the solution was filtered immediately and the filtrate titrated with twice-normal hydrochloric acid in presence of methyl orange and phenolphthalein. After standing for 2 days another portion of the solution was filtered and titrated in the same way.

"In system (1) barely one-third of the phosphoric acid present is precipitated, in the form of tri- and tetrabasic salts, and not two-thirds in the form of a double salt  $\text{Ca}_3(\text{Ba}_3)\text{Na}_6(\text{PO}_4)_4$ , as Berthelot stated. Two-thirds of the phosphoric acid remains in solution in the form of tri- and di-basic salts. The bases are distributed irregularly between the precipitate and the solution. If the system  $1\text{H}_3\text{PO}_4 + \frac{1}{2}\text{BaO} + 2\text{NaOH}$  be allowed to stand for a long time, the precipitate ultimately contains one atomic proportion each of sodium and barium, and nearly one-half of the acid is precipitated. In system (2) also, the bases are distributed irregularly between the precipitate and the solution. The latter contains mono- and dibasic phosphates, whilst the precipitate contains di-, tri-, and, occasionally, tetrabasic salts. Less than two-thirds of the phosphoric acid is precipitated.

"Magnesia behaves differently from lime and baryta, and its behavior depends also on the kind of alkali present. For example, in system (3) when the alkali employed is sodium hydroxid, the precipitate consists solely of magnesium compounds, whilst when potassium hydroxid is used, some alkali is carried down by the precipitate. In system (4) much less phosphoric acid is precipitated (only about

one-sixth of the total quantity); apparently a soluble double phosphate is formed, as dimagnesium phosphate is insoluble, and the amount of alkali present would be sufficient for the precipitation of the remaining dissolved magnesium under ordinary conditions."

**The reactions of the three phosphoric acids**, C. ARNOLD and G. WERNER (*Chem. Ztg.*, 29 (1905), No. 104, pp. 1326, 1327; *Analyst*, 31 (1906), No. 360, pp. 92, 93).—The authors' tests of published reactions having shown them to be generally unreliable, a new series of tests with the alkali salts of ortho-, pyro-, and metaphosphoric acids is given.

**On the compounds of pyrophosphoric acid**, J. CAVALIER (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 15, pp. 885-887).—Four series of salts of this acid, which is taken to be tetrabasic ( $P_2O_5H_4$ ), are briefly described. Studies of the vapor densities of a series of alcoholic pyrophosphates show that they have a molecular weight corresponding closely with the formula  $P_2O_5R_4$ .

**On the determination of citric-acid soluble phosphoric acid in Thomas slag**, H. FRESSENIUS (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 12-15).—A brief review is given of studies of this method.

**The determination of phosphoric acid in fertilizers as phosphomolybdic anhydrid**, G. BERLU (*Jour. Landw.*, 54 (1906), No. 1, pp. 31-46; *abs. in Chem. Ztg.*, 30 (1906), No. 24, *Rept.* No. 7, p. 94).—This article reports a study of the accuracy of Neumann's method<sup>a</sup> as applied to pure phosphates and Thomas slag solutions prepared in various ways. The method is reported to have given accurate results under all conditions and is much simpler and more accurate than direct precipitation of phosphoric acid as magnesium-ammonium phosphate.

**The determination of ammoniacal nitrogen in ammoniated superphosphates**, SCHEELE and VON SOXHLET (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 15-17).—A brief account is here given of the discussion of methods for this purpose at the Munich meeting of the Association of German Agricultural Experiment Stations.

**A simple method for the determination of nitric acid in nitrates**, J. T. BORNWATER (*Chem. Weekbl.*, 3 (1906), pp. 30, 31; *abs. in Chem. Centbl.*, 1906, I, No. 8, p. 703).—In the method proposed the nitrate is reduced by means of potash solution and aluminium foil and the ammonia distilled in a Kjeldahl apparatus.

**On the need of uniform methods of titration in the determination of nitrogen**, B. SCHULZE (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 35, 36).—A brief account of the discussion of this subject at the Munich meeting of the Association of German Agricultural Experiment Stations, calling attention to lack of uniformity in kind and strength of acids and alkalis used and of the desirability of greater uniformity in these respects.

**The determination of potash by means of perchloric acid** (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 6, 7).—This method is described and its unanimous adoption by the Association of German Agricultural Experiment Stations is recorded.

**The detection and determination of chlorate in sodium nitrate**, L. GRIMBERT (*Jour. Pharm. et Chim.*, 6. ser., 23 (1906), pp. 98-100; *abs. in Analyst*, 31 (1906), No. 361, p. 128).—Sodium nitrate is tested for presence of chlorate by shaking up the solution with 1 drop of anilin, and pouring a little strong sulphuric acid down the side of the tube. If chlorate is present an intense blue zone appears at the junction of the liquids. Chlorate is determined quantitatively by igniting the nitrate with a little cane sugar, extracting with water, and titrating for chlorids in the usual way.

**On the gravimetric determination of calcium**, O. BRUNCK (*Ztschr. Analyt. Chem.*, 45 (1906), No. 2, pp. 77-87, fig. 1).—Comparisons of various methods—direct weighing, weighing as carbonate, sulphate, and fluorid—of determining lime are reported. Direct weighing gave the most unsatisfactory result—generally too high.

<sup>a</sup> *Ztschr. Analyt. Chem.*, 37 (1898), p. 317.

The other three methods gave closely agreeing results and were about equally satisfactory. The fluorid method is probably the quickest and most satisfactory in the hands of beginners. For control purposes it is recommended to weigh first as carbonate and then convert into sulphate or fluorid.

**Determination of lime in soils**, D. J. HISSINK (*Chem. Weekbl.*, 3 (1906), pp. 73-78; *abs. in Chem. Centbl.*, 1906, I, No. 11, p. 961).—Neubauer's method is recommended.

**The analysis of foods. Simple and easy methods of detecting adulteration of food products and other domestic articles**, C. MARGEOT (*L'analyse des aliments. Recettes simples et faciles pour découvrir toutes les falsifications des produits alimentaires et autres objets domestiques. Paris: E. Flammarion, pp. 188*).—As the subtitle states, this volume gives simple directions for the detection of adulteration of food products and other materials used in the home. The descriptive matter includes standards of quality of staple articles of food, the principal methods of adulteration and sophistication which are likely to occur, and methods of detection of adulteration.

**The use of the immersion refractometer in food analysis**, J. HANUŠ and K. CHOCENSKÝ (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 6, pp. 313-320, fig. 1).—The experimental data described show that the immersion refractometer may be used to determine the amount of caffeine present in aqueous solution quickly and accurately.

**Maple sirup and maple sugar investigations with particular reference to the detection of adulteration**, C. H. JONES (*Vermont Sta. Rpt. 1905, pp. 315-339*).—A number of samples of maple sugar and sirup, maple cream, and brown sugars were examined with special reference to the amount and character of the ash present, the malic acid value, the amount of precipitate obtained with lead subacetate, and other characteristics, the object of the investigations as a whole being the detection of adulteration, particularly with cane and beet sugar products.

According to the author, the minimum standards which seem warranted when applied to a filtered sirup weighing 11 lbs. to the gallon are not less than 0.50 per cent total ash, not less than 0.15 per cent insoluble ash, not less than 0.40 per cent malic acid value, nor less than 1.00 cc. for the lead subacetate precipitate.

If an examination of an original sample shows that one or all of such salient factors are below the minimum, the samples should be boiled to a uniform basis of concentration and filtered. It would seem, the author states in effect, that a certain minimum amount of ash can not be removed from pure maple sirup or maple sugar made into sirup, by the ordinary methods of filtration, and that even slow and complete filtering fails to remove sufficient ash from the pure goods to admit even a suspicion of adulteration.

The ash of pure maple goods consists largely of carbonates of potassium and lime with relatively small and varying quantities of sulphates and phosphates. The determination of the sulphates, according to the author, is of use at times in detecting adulteration since they are present in relatively large amounts in many commercial brown, cane, and beet sugars.

"The amounts of lime and potash also afford data useful in judging the purity of suspected samples. Owing to the work involved these determinations are needful only in important cases when other tests do not furnish convincing data.

"It has been observed that the percentage of sulphates appears to be greater in maple sirup than in maple sugar, although no explanation has been offered. In the writer's opinion, it may be accounted for as follows: The percentage of ash, soluble in water, is greater in sirups than in sugars. . . . This is due entirely to the larger quantity of malate of lime (insoluble ash) in the sugar. As sulphates are found largely in the soluble ash, they would therefore average greater on an ash basis in sirups than in sugars.

"The author has yet to see a pure maple sirup that, even after souring or long keeping under any reasonable conditions, will not furnish an abundant maple aroma on boiling after dilution with water. The flavor or taste of maple goods may serve in a measure to indicate their purity. Inasmuch as many pure maple sirups, particularly those produced in certain sections of the country, have what might be termed a 'molasses taste,' it is best not to form hasty opinions from this sense alone, especially if the origin, age, and conditions of manufacture are not known. The flavor taken into consideration with color is a good criterion as to quality of maple products." (For earlier work see E. S. R., 17, p. 219).

**The examination of honey,** H. MATTHIES and F. MUELLER (*Ber. Nahrml. Untersuch. Amt. Jena*, 1903-4, pp. 37-45; *abs. in Ztschr. Untersuch. Nahr. u. Genussm.*, 9 (1905), No. 12, pp. 739-741).—Detailed directions are given for determining the different constituents and constants desirable in an analysis of honey, a feature of the work being the recommendation that a uniform solution of honey be used in every case. The author prepares the solution by dissolving 5 gm. of warm well-mixed honey in 50 gm. of warm water and then diluting to 150 gm. The results of the analyses are all expressed on the dry-matter basis.

**Concerning starch, glycogen, and cellulose,** Z. H. SKRAUP (*Monatsh. Chem.*, 26 (1905), No. 11, p. 1415; *abs. in Zentbl. Physiol.*, 20 (1906), No. 1, pp. 1, 2).—The chlorazetyl products of starch, glycogen, and cellulose were made by treatment with acetic-acid anhydrid saturated with hydrochloric acid.

From the chlorin content of the bodies formed it is possible to secure data regarding molecular weight. The calculated molecular weight for soluble starch was 7,440, which implies that the starch formula is 46 to 50 times  $C_6H_{10}O_5$ . The calculated molecular weight for glycogen was 23,630, which would imply a very complicated molecular structure. The values obtained for cellulose from filter paper indicate that the formula is not higher than for soluble starch, perhaps  $(C_6H_{10}O_5)_{34}$ .

**Chemistry of the albumens,** S. B. SCHRYVER (*Philadelphia: P. Blakiston's Son & Co.*, 1906; *rev. in Jour. Amer. Chem. Soc.*, 28 (1906), No. 5, pp. 658-660).—The present knowledge of the chemistry of proteids is summarized.

"Facts relating to the solubility, physical properties, precipitation by salts, coagulation, behavior toward acids and bases, etc., which have, in the past, formed so large a part of the accounts that have been written of these bodies occupy in this book but a very insignificant place. This fact shows the great progress made during the past five years in our knowledge of the chemical side of this subject, for it is now possible to give a condensed account of the purely chemical facts that are known which is sufficiently extensive to warrant their publication in a separate volume."

A considerable part of the volume is taken up with the chemistry of the nucleic acids and their decomposition products, especially the purin and pyrimidin bodies, which bear no chemical relation to the protein molecule proper. "The only reason for including the nucleic acids is the fact that they are always found in nature together with the proteins or the protamins. This practice, while convenient for those familiar with the proteins, leads to confusion among those who take only a general interest and read such books as the one under consideration in order to obtain a general knowledge of the chemistry of the proteins."

**Crude gluten,** F. A. NORTON (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 1, pp. 8-25).—According to the author's investigations "crude gluten consists of about 75 per cent of true gluten—gladin and glutenin—together with small percentages of nongluten proteid, mineral matter, fat, starch, fiber, and other nonproteid matter.

"The relation of the crude gluten content to that of total protein ( $N \times 5.7$ ) varies with the character of the flour, the crude gluten content being greater than total protein for straight and low-grade flours, nearly the same for patent flours, and less for whole-wheat meal.

"Crude gluten is an expression, in addition to the true gluten content of a flour, of the balance between the loss of nongluten proteids and gain from the retention of nonproteid substances. The relation of the crude gluten content to the total protein content can thus be explained by the varying composition of the different flours in respect to nitrogenous compounds and nonproteids.

"Crude gluten is a very rough expression of the gluten content of a flour or wheat and the determination has but little worth in the valuation of flours.

"The determination of total nitrogen and gliadin nitrogen with expression of the ratio of gliadin to total protein ( $N \times 5.7$ ) seems to be the best simple method at hand for estimating the gluten content and ascertaining the character of the gluten in the valuation of wheats or flours."

**Determining the sulphurous acid in meat**, C. MENTZEL (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 11 (1906), No. 6, pp. 320-324).—In a number of cases the distillation method showed the presence of small amounts of sulphurous acid (5 to 7.8 mg.) in chopped meat when it could not be identified by means of potassium-iodid-starch paper.

**The estimation of undigested protein in feces by means of thiosinamin acid**, E. ROSENBERG (*Arch. Verdauungskrank.*, 11, p. 321).—Oefele's method of estimating undigested protein is, according to the author's investigations, not reliable.

**Concerning the composition of lecithin**, M. WINTGEN and O. KELLER (*Arch. Pharm.*, 244 (1906), No. 1, pp. 3-11).—Studies of the phosphorus and nitrogen content of lecithins of animal and vegetable origin are reported. The purity of lecithin can not be ascertained by determining the nitrogen and the phosphorus content alone. Whether the determination of the iodine value and the free fatty acid value will serve for the purpose must be determined by further investigation.

**General and physiological chemistry of fats**, F. ULZER and J. KLIMONT (*Allgemeine und physiologische Chemie der Fette*. Berlin: J. Springer, 1906; rev. in *Österr. Chem. Ztg.*, 9 (1906), No. 9, p. 128).—A monograph on the chemistry of fats from the standpoint of theoretical and physiological chemistry. A feature of the work is the data on the qualitative chemical composition of the fats. Chapters on the hydrolytic cleavage of fat from the standpoint of physical chemistry, by E. Abel, and on the cleavage of fat by enzymes, by S. Fokm, are included.

**Concerning the estimation of fat in oil-bearing seeds**, F. RUPPEL (*Ztschr. Analyt. Chem.*, 45 (1906), No. 2, pp. 112-114).—The modified method proposed consists in extracting the bulk of the fat by treating the finely ground seed for 6 hours with ether, then drying the undissolved residue, grinding with quartz sand, and extracting aliquot portions until all fat is removed.

**Contribution to the examination of butter**, M. SIEGFELD (*Milchw. Zeitbl.*, 2 (1906), No. 4, pp. 145-164, *dgms.* 5).—This is a continuation of investigations previously noted (*E. S. R.*, 17, p. 9).

The data obtained in the examination of the butter from 2 dairies for several years are used as the basis for a discussion of the relative value of determinations of the Reichert-Meissl number, Polenske number, saponification number, iodine number, and the average molecular weight of the fatty acids in the examination of butter. In general, an increase in the Reichert-Meissl number was accompanied by an increase in the saponification number and a decrease in the iodine number, and in the average molecular weight of the nonvolatile fatty acids. The sample having the lowest Reichert-Meissl number, 23.7, had a saponification number of 218.7, an iodine number of 47.4, and an average molecular weight of 269.9. The sample having the highest Reichert-Meissl number, 31.65, had a saponification number of 229.9, an iodine number of 34.6, and an average molecular weight of 257.6.

**A simple method of determining fat in milk**, KÜTTNER and ULRICH (*Ztschr. Öffentl. Chem.*, 12 (1906), No. 9, pp. 162-166).—Numerous tests were made of the Siehler method in comparison with other methods, the results being considered as showing that this method is a decided improvement over the rapid methods previously used.

**Gerber's salt method**, C. BEGER (*Milchw. Zentbl.*, 2 (1906), No. 3, pp. 120-123).—The author reports favorably upon the use of this new method of determining fat in milk.

**The influence of acetic acid and alcohol in gravimetric determinations of the total solids in milk**, A. SÉGIN (*Milchw. Zentbl.*, 2 (1906), No. 3, pp. 115-119).—The author uses the covers of porcelain crucibles from which the small central handles have been broken off, measuring into each cover about 2.5 cc. of milk, and rapidly weighing the sample. The milk is then evaporated over a water bath and the residue dried to a constant weight in a water oven at 100° C., which requires about 4 hours. No absorbent material is used.

The time required for drying to a constant weight was increased by the addition of acetic acid and alcohol and higher results were usually secured. The direct drying in small porcelain dishes is recommended as one of the most accurate, convenient, and reliable methods for determining solids in milk.

**On the watering of wine and milk**, L. SURRE (*Ann. Chim. Analyt.*, 11 (1906), No. 5, pp. 163-165). The methods given for the detection of added water depend upon the diphenylamin reaction for nitrates, which is not given by these materials when pure.

**Collaborative work on tannin analysis**, F. H. SMALL (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 7, pp. 296-298).—This is a brief review of the work of several associations on the methods of estimating tannin. A fairly satisfactory method, the principles of which are given, has resulted, according to the author, from this collaborative work. The various lines of work of the American Leather Chemists' Association now in progress are outlined.

**Miscellaneous chemical analyses made in 1901**, A. M. PETER and L. O. BEATTY (*Kentucky Sta. Rpt.* 1901, pp. 263-295).—Analyses are reported of 49 samples of sorghum juice, 22 of butter, 27 of sugar beets, 17 of soils, 7 of feeding stuffs, 9 of common salt, 4 of crude petroleum, 1 of marl, 2 of phosphate rock, 4 of clay, 4 of ashes, 2 of tobacco stems, 1 of a tobacco by-product, 5 of tobacco extract, 3 of Paris green, 1 of a commercial substance recommended for use in curing tobacco, 5 of Kentucky asphalt rock, 1 of iron ore, and 24 of mineral waters. Determinations were also made of the arsenic in 6 samples of sprayed cabbage.

**Miscellaneous chemical analyses made in 1902**, A. M. PETER, L. O. BEATTY, and S. D. AVERITT (*Kentucky Sta. Rpt.* 1902, pp. 283-335).—Analyses are reported of 16 samples of sorghum juice, 31 of sugar beets, 10 of butter, 27 of soils, 1 of old wood ashes, 61 of grasses and forage plants, 6 of soy beans, 1 of mushrooms, 2 of cotton-seed meal, 1 of a calf food, 1 of distillers' corn bran, 1 of dried distillers' grains, 5 of distillery slop, 5 of clay, 2 of niter earth, 1 of dissolved bone, 1 of agricultural lime, 1 of cow manure, and 42 of mineral waters.

**Miscellaneous analyses**, C. H. JONES and F. M. HOLLISSER (*Vermont Sta. Rpt.* 1905, pp. 339, 340).—Analyses of a number of miscellaneous materials, including nitrate of soda, dried blood, tankage, bone (raw and steamed), acid phosphate, muriate of potash, wood ashes, muck, and mixed fertilizers, are reported.

## METEOROLOGY—WATER.

**Monthly Weather Review** (*Mo. Weather Rev.*, 34 (1906), Nos. 1, pp. 1-60, figs. 19, charts 8; 2, pp. 61-108, figs. 9, charts 28).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of January and February, 1906, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 1.—The Cyclonic Storm of October 6-12, 1905, in the North Atlantic Ocean (illus.), by J. Page; Improved Methods for Finding Altitude and Azimuth, Geo-

graphical Position, and the Variation of the Compass—Second Article (illus.); Studies on the Thermodynamics of the Atmosphere—I, Asymmetric Cyclones and Anticyclones in Europe and America (illus.), by F. H. Bigelow; Atmospheric Electricity, by G. C. Simpson; Atmospheric Electricity in High Latitudes, by G. C. Simpson; The Time of Moonrise and Moonset (illus.), by W. F. Rigge; A Possible Extension of the Period of Weather Forecasts, by E. B. Garriott (see p. 1045); Forecasts and Verifications in Western Australia, by W. E. Cooke; The Relation of Forests to Rainfall (illus.), by W. F. Hubbard (see p. 1044); An Important Old Local Weather Record for Philadelphia, Pa.; An Appeal for an Aero-physical Observatory in Japan, by S. T. Tamura; Tornadoes—Hailstones—Thunderclouds, by J. P. Gibson; and Weather Bureau Men as Educators.

No. 2.—The Relation between Storm Movement and Pressure Distribution (illus.), by E. H. Bowie; Climatology of Haiti in the Eighteenth Century (illus.), by C. F. Talman; Mean Annual Rain Map of New South Wales; Studies on the Thermodynamics of the Atmosphere—II, Coordination of the Velocity, Temperature, and Pressure in the Cyclones and Anticyclones of Europe and North America (illus.), by F. H. Bigelow; Vertical Air Currents, by F. W. Proctor; Snow Formed by Mixture of Warm and Cold Air, by R. W. Gray; Prevention of Damage by Frost, by R. P. Skinner (see p. 1044); Early Knowledge of the Tides at Panama, by R. A. Harris; Publication of River Gage Readings; Weather Bureau Men as Educators; Life and Work of James P. Espy; Lectures on Meteorology; Hailstorms in the Bahamas; A Fake Rain Maker; and Outline for the Study of Meteorology in the New York State Normal School.

**Meteorological observations** (*Idaho Sta. Rpt. 1905, pp. 36-48*).—Daily and monthly summaries are given of observations during 1905 on temperature, pressure, precipitation, cloudiness, and wind movement. The mean temperature of the year was 48.6°, the highest temperature 103°, July 22; the lowest -13°, February 11; the total precipitation (rainfall and melted snow) was 20.37 in., the rainfall being 17.51 in.

**Meteorological summaries for the year 1901** (*Kentucky Sta. Rpt. 1901, pp. 296-301*).—Tabular summaries for 1901 are given of observations at the station on pressure, temperature, precipitation, cloudiness, wind movement, and casual phenomena.

**Meteorological summaries for the year 1902** (*Kentucky Sta. Rpt. 1902, pp. 336-341*).—Tabular summaries for 1902 are given of observations at the station on pressure, temperature, precipitation, cloudiness, wind movement, and casual phenomena.

**Meteorological observations** (*Maine Sta. Bul. 124, pp. 229-231*).—Monthly and annual summaries are given of observations at the experiment station on pressure, temperature, precipitation, cloudiness, wind movement, and of rainfall at 24 different places in the State. The mean pressure for the year was 29.84 in., the mean temperature 42.13° (normal for 37 years 42.2°), precipitation 32.01 in. (normal for 37 years 43.98 in.), snowfall 70.5 in. (normal for 37 years 91.6 in.), number of clear days 150, cloudy days 121.

"The winter of 1904-5 was one of unusual severity, December being 4½°, January 3°, and February 4° below the average for these months. . . . During this same period the thermometer registered zero or below, as the minimum temperature, on no less than 50 days.

"For three successive years the total precipitation has been very low, the deficit for the past year amounting to about 12 in., or over one-fourth of the whole. The shortage was especially noticeable in March and October, in which months the precipitation was about one-fifth the average. In but one month of the year, November, did the precipitation equal the average amount."

**Meteorological observations**, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Met. Buls.* 207, 208, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1906. The data are briefly discussed in a general note on the weather of each month.

**Meteorological observations at the Michigan Agricultural College for the year 1904** (*Michigan Sta. Rpt. 1905*, pp. 99-123).—Tabulated daily and monthly summaries of observations during 1904 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

**Swedish meteorological observations, 1904**, H. E. HAMBURG (*Met. Iakttag. Sverige [Observ. Mët. Sué.]*, K. Svenska Vetensk. Akad., 46 (1904), pp. X+157).—This report is divided into 3 parts, (1) daily observations at 18 stations of the second order, (2) monthly and annual summaries of all the meteorological elements furnished by 39 stations of the second order, and (3) 5-day means of temperature at the 39 stations included in part 2.

**Meteorological observations for the year 1904 at the Ploti Agricultural Experiment Station**, M. SVOLINSKY (*Ghodichnui Otchet Ploty. Selsk. Khoz. Opušn. Stantzū*, 10 (1904), pp. 1-25).—As in previous years (*E. S. R.*, 16, p. 544), this report summarizes observations on precipitation (including snowfall), evaporation, humidity of the air, temperature of the air and of the soil at different depths, insolation and solar radiation, atmospheric pressure, and direction of wind. The total precipitation during the year was 299.4 mm., the smallest for the ten years during which observations have been made at the station. The distribution of the rainfall, however, was favorable for the growth of crops. The mean annual temperature of the air was below normal. The maximum temperature was 35.1° C., July 18; the minimum, -23.2°, January 11 and 13. The maximum pressure during the year was 764.6 mm., the minimum 728 mm. The prevailing direction of wind was northwest.

**Observations at the meteorological observatory of the University of Innsbruck in 1902**, W. TRABERT (*Ber. Naturw. Med. Ver. Innsbruck*, 29 (1903-4, 1904-5), pp. 277-337).—Detailed tabular records of daily observations on atmospheric pressure, temperature, humidity, cloudiness, wind, and precipitation, and hourly observations with self-recording apparatus on pressure, temperature, humidity, rainfall, and sunshine are given for each month of the year.

**International Meteorological Conference at Innsbruck** (*Nature [London]*, 72 (1905), Nos. 1873, pp. 510-512; 1875, pp. 562, 563; 73 (1906), No. 1892, pp. 331, 332).—A summary account of proceedings of this conference held at Innsbruck September 9-15, 1905, under the presidency of J. M. Pernter.

In his opening address the president discussed particularly the importance and progress of exploration of the upper air and the problem of weather periods and their connection with and dependence on the activity of the sun. Among the subjects receiving particular attention were investigations of excessive rainfall, solar radiation, long series homogeneous observations, meteorological observations during the last century, island meteorological stations, and use of wireless telegraphy to announce the approach of storms.

**Japanese meteorological service in Korea and China**, S. T. TAMURA (*Science*, n. ser., 23 (1906), No. 584, pp. 396, 397).—The organization of a series of stations under the supervision of the Chemulpo Meteorological Observatory and their equipment are briefly described.

**Climatic notes on the Sahara**, E. F. GAUTIER (*Ann. Géogr.*, 14 (1905), No. 78, pp. 459-461; *Bul. Amer. Geogr. Soc.*, 38 (1906), No. 1, pp. 32-34; *abs. in Science*, n. ser., 23 (1906), No. 588, p. 555).—The more important climatic facts brought out in this report are that strictly desert conditions are not as extensive in the Sahara as is generally believed; and that there have been three epochs in the climatic history

of the region, the first marked by conditions which supported a dense population (of the neolithic period), the second by desert conditions, and the third, or present period, in which the land is gradually assuming a steppe-like character.

The gradual desiccation of the region advanced from the Soudan, but to-day the rainbelt is again extending more and more toward the north. On the steppes, where the Soudan merges into the Sahara, the annual rainfall is 6 to 12 inches and supports considerable vegetable and animal life.

**Texas rainfall during 1905** (*Texas Farm and Ranch*, 25 (1906), No. 10, p. 3, fig. 1).—A map with brief notes furnished by E. E. Spencer, director of the Texas section of the Weather Bureau, is given. The average annual precipitation for the State as determined from reports of 87 stations was 44.49 in., or 12.55 in. above the normal. The greatest annual precipitation was 86.32 in. at Jefferson, the least 17.8 in. at El Paso. The heaviest rainfall occurred over the eastern, northeastern, central, and coast regions of the State.

**Rainfall in the agricultural districts**, G. G. BOND (*Queensland Agr. Jour.*, 16 (1906), No. 5, p. 380).—A table is given which shows the total rainfall for each month from December, 1904, to December, 1905, inclusive, in 41 agricultural districts of Queensland.

**The relation of forests to rainfall**, W. F. HUBBARD (*Mo. Weather Rev.*, 34 (1906), No. 1, pp. 24-26, figs. 2).—The distribution of forests as dependent upon rainfall is illustrated by conditions in California, and it is shown that "topography and winds are the controlling factors in the distribution of forests. They make most of the Pacific coast a region of winter rains and summer droughts, and, away from the coast, limit the forests to the higher altitudes. . . . As rainfall determines the presence or absence of forests, so the configuration of the land and its relation to water bodies and constant winds determine the rainfall."

**Forests and rainfall in Silesia**, J. SCHUBERT (*Ztschr. Forst u. Jagdw.*, 37 (1905), No. 6, pp. 375-380, figs. 3; *abs. in Met. Ztschr.*, 22 (1905), No. 12, pp. 566-570, figs. 3, and *Science*, n. ser., 23 (1906), No. 589, p. 593).—This subject is discussed on the basis of the rainfall map published by Hellmann in 1899, the conclusion reached being that forests seem to produce an increase in precipitation. This is ascribed to the fact that forests retard wind movement and promote rise and cooling of the air. If one-half of the observed difference is set down as being due to the increased protection of the gauges set up in or near the forests, the actual effect of the trees themselves would roughly correspond to an increase in altitude of 40 meters.

**Prevention of damage by frost**, R. P. SKINNER (*Mo. Weather Rev.*, 34 (1906), No. 2, pp. 79, 80).—Tests of various smudges and the use of potash salts as fertilizers are reported, which, while not conclusive, indicate that more or less protection may be afforded in some cases by such means.

**Cloud studies**, A. W. CLAYDEN (*London: John Murray*, 1905, pp. XIII + 184, pls. 61; *rev. in Nature* [London], 73 (1906), No. 1896, pp. 416, 417, figs. 2).—In his review of this book Prof. H. H. Hildebrandsson states that it will be a standard work for all students of clouds. The author accepts the types of the International Cloud Atlas and arranges his various forms as subforms of these types with the exception of the nimbus cloud, which he classifies as a subform of the stratus type.

**On cloud formation in the Alpine valleys**.—Contributions to the mechanism of cloud formation, H. VON FICKER (*Ber. Naturw. Med. Ver. Innsbruck*, 29 (1903-4, 1904-5), pp. 193-275).—A series of observations at various elevations to study especially the formation of stratus clouds in inland valleys is reported.

**Apparatus for observing and recording storms** (*Sci. XX. Siècle*, 1905, Aug. 15, Sup.; *abs. in Rev. Sci. [Paris]*, 5. ser., 5 (1906), No. 9, pp. 278, 279).—An apparatus devised by A. Turpain, of the meteorological observatory of Puy-de-Dôme for photographically and automatically recording the electrical condition of the atmosphere during storms is described.

**A possible extension of the period of weather forecasts**, E. B. GARRIOTT (*Mo. Weather Rev.*, 34 (1906), No. 1, pp. 22, 23).—A study of counterbalancing tendencies with regard to weather abnormalities in different parts of the globe leads to the conclusion that with completion of daily telegraphic communication with the dominating "centers of atmospheric action" over Siberia, the Alaskan coast, the Azores, and Iceland, "daily available forecasts can undoubtedly be made of the general character of the weather for at least one week in advance. Such general forecasts could specify the character, whether warm or cold, wet or dry, of the weather of the near future, and could indicate the duration and termination, days in advance, of periods of abnormal weather."

**Public water supply of Ohio** (*Ann. Rpt. Bd. Health Ohio*, 19 (1904), pp. 61-343).—Reports are given on plans for water supplies or sewerage proposed during 1904 for a large number of places in Ohio.

The results of laboratory examination of waters, sewage, and sewage effluents, and studies of methods of purification are also reported in detail.

It is stated that "with but few exceptions the surface waters of the State are unsuited for a public supply. In many regions the ground water is inadequate for a city of much size. The purification of surface waters must receive more and more attention. A filtration plant must be properly constructed and efficiently operated to afford a safe water supply."

It is suggested that "it would seem not improper for the State Board of Health to collect the evidence to show that the water supply of any city is dangerous to life and health. The attorney-general might present this evidence to a court of competent jurisdiction—to the supreme court, if possible. If satisfied that conditions were such that public interests warranted and demanded it, this court should have authority to compel the city to make necessary improvements within a reasonable time."

Seventy-one cities and 177 villages, representing 55 per cent of the population of Ohio, had a public water supply in 1904.

**The sources of water supply in Wisconsin**, W. G. KIRCHOFFER (*Bul. Univ. Wis.*, No. 106, pp. 163-267; *abst. in Engin. News*, 55 (1906), No. 13, pp. 355, 356).—It is stated that of the 270 cities and villages in Wisconsin 120 are provided with a public water supply. Fifty of the latter use artesian water, 30 ground water, 14 lake water, 12 river water, and of the remainder the source of supply is not definitely known. Of the artesian well supplies, 27 are from Potsdam sandstone, 10 from St. Peters sandstone, and the remainder from both.

As regards the amount of water used from the various sources, lake waters rank first, artesian waters second, ground waters third, and river waters fourth. As to sufficiency or quantity, lake waters rank first, river waters second, artesian waters third, and ground waters fourth, and as to purity, artesian waters rank first, lake waters second, ground waters third, and river waters fourth. The most serious troubles with artesian waters were hardness and presence of iron.

**The biology of water bacteria**, E. KOHN (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1906), Nos. 22-23, pp. 690-708, figs. 3; 25, pp. 777-786).—This article reports studies on the general course of multiplication of micro-organisms and changes in the composition of the bacterial flora when water is allowed to stand and the food requirements of a series of saprophytic fresh-water micro-organisms.

The bacterial flora was found to change quantitatively and in composition when large samples of sweet water were allowed to stand for a long time. The increase in germination was greatest in vessels of the kinds of glasses which were the most soluble in water. The phosphorus thus dissolved from the glass was sufficient for the requirements of the organisms. The organisms were found to vary widely with regard to their behavior toward the nutrient solutions, particularly the concentration of grape

sugar and ammonium sulphate solutions supplied. Three per cent grape-sugar solution was found to be too strong for *Urobacillus pasteurii*.

**Experiments with copper-iron sulphate for water purification at Marietta, Ohio** (*Engin. Rec.*, 53 (1906), No. 12, pp. 392-394, figs. 4).—The successful use of a mixture of copper and iron sulphates precipitated with caustic lime and held on the filter for precipitation of impurities and reduction of the number of bacteria in water is reported.

### SOILS—FERTILIZERS.

**Soils**, T. DIETRICH and F. HONCAMP (*Jahresber. Agr. Chem.*, 3. ser., 7 (1904), pp. 25-99).—A review is given of the literature relating to this subject published during 1904, classified as follows: Rocks, stones, and their weathering products; cultivated soils, including analyses of soils, physics of soils and absorption, and the lower organisms of soils; and moors and moor culture.

**Mechanical analysis of soils**, J. A. MURRAY (*Chem. News*, 93 (1906), No. 2409, pp. 40-42; *abs. in Analyst*, 31 (1906), No. 361, pp. 129, 130).—This article describes "a long tube sedimentation process."

The apparatus employed consisted of an Erlenmeyer flask (of about 200 cc. capacity) of which the neck, after removal of the flange, was exactly the same diameter as a long glass tube which was attached to it by means of a piece of india-rubber tubing fitted outside of the tube and of the neck of the flask. The tube actually used was 147 cm. long by 2.3 cm. internal diameter. "A wide shallow glass basin about 20 cm. diameter and a few small porcelain evaporating dishes about 7.5 cm. diameter are also necessary. . . .

"The experiment was carried out as follows: Five gm. of the air-dried fine soil (i. e., that which had passed through 100-mesh sieve), thoroughly disintegrated in dilute ammonia solution, was put into the flask, which was then vigorously shaken, filled nearly full of water, and attached to the tube. Water was then poured gently down the side of the tube (so as not to disturb the sediment in the flask) till it also was full, when the open end was closed with a cork, and the whole inverted over the large basin of water. The cork closing the end was immediately withdrawn, and one of the small porcelain evaporating dishes, previously dried and weighed, placed beneath the open end of the tube.

"The sediment began to descend whenever the tube was inverted, and the first particles were deposited in the dish in about fifteen seconds. After a short interval this dish, containing the first portion, was removed and replaced by another, and this again by a third, and so on. These dishes containing the several fractions of the sediment thus removed from the large basin were of course full of water, of which, however, a considerable part was separated by simple decantation, after standing for a few minutes, and the remainder driven off on the water bath. The dried residue was then weighed, and examined under the microscope for determination of the size of the particles."

Results of tests of the method on a sample of stiff clay soil and of Rothamsted soil are reported.

It was found advisable in case of the heavier soil to make a preliminary rough separation of the finer and coarser material by shaking with weak ammonia, allowing to stand 15 minutes, and pouring off the solution containing the fine material in suspension. The coarser material was introduced into the apparatus described and separated into 3 fractions, viz, those separating in 5, 15, and 40 minutes after the beginning of the test. Preliminary separation was not necessary in case of the lighter Rothamsted soil.

**A chemical study of some Oregon beaver-dam soils**, C. E. BRADLEY (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 1, pp. 64, 65).—Analyses of 5 samples of beaver-dam

soils of the Willamette Valley, one of which is virgin and the others have been used for a number of years in onion growing, are reported.

These soils when virgin are composed largely of organic matter of a peaty nature. They are porous, light, and loose, with no tendency to bake or form lumps. The analyses show that their nitrogen content is large. Potash is present in liberal quantities, but is of low availability. Phosphoric acid is not deficient and is largely in available form. The soils contain sufficient lime to keep them sweet, and lime is always in excess of magnesia.

The nitrogen content of the virgin soil was 1.56 per cent and varied from 0.78 to 2.06 per cent in 3 of the cultivated soils. The total potash content was 0.14 per cent in the virgin soil and varied from 0.1 to 0.28 per cent in the other soils. The phosphoric-acid content was 0.26 per cent in the virgin soil, varying from 0.21 to 2.3 per cent in the cultivated soils. The availability of the potash and phosphoric acid was determined by digestion in 0.5 per cent hydrochloric acid.

**Report on the soils of Dorset, with suggestions on manuring, cultivation, etc.,** J. PERCIVAL (*Univ. Col. Reading, Agr. Dept., Ann. Rpt. Soils Dorset*, 7 (1905), pp. 50, map 1).—This report summarizes in a simple manner the more practical results of the analyses of 100 samples of soil from various parts of Dorsetshire which have been previously reported (*E. S. R.*, 15, p. 857), the information being adapted especially to those engaged in farming in Dorset.

"The first part of the report contains general information as to manures. In this part will be found a description of some of the chief kinds of manures and suggestions as to the use of manures for various crops. Some notes on grass mixtures are also given. The second part of the report contains a description of the various kinds of soils in the county according to their geological formations; and suggestions are given on points connected with the manuring and cultivation of each class of soil, largely based upon the analyses of typical soils, of which a list (with the results) is given for each district."

A geological map is given which makes it possible to locate the different classes of soils discussed. It is shown that a large proportion of the area consists mainly of chalk formation, while another large area is occupied by a series of sands of low fertility. The chief deficiency of the chalk soils seems to be potash.

**On loess soils and loess marls,** HALENKE, KLING, and ENGELS (*Vrtljschr. Bayer. Landw. Rat.*, 10 (1905), No. 3, pp. 447-455).—This article describes the various types of loess occurring in the Rhenish Palatinate and discusses their origin and transformations, especially their changes in lime content. Examinations of a large number of samples show a variation of 0.08 to 6.05 per cent of lime in the surface soil and 0.19 to 47 per cent in the subsoil, ranging from pure sandy loess to loess marl. The chemical and physical make-up of the latter is considered in detail.

**The fertilizer requirements of Hessian soils,** E. HASELHOFF (*Das Dungungsbedürfnis der hessischen Boden*, pp. 39; *Fühling's Landw. Ztg.*, 55 (1906), No. 3, pp. 73-81).—The composition and fertilizer requirements, as determined by pot experiments, of Hessian soils of different geological origins are discussed.

The soils tested were of basalt, bunter-sandstein, shell lime, graywacke, and clay slate types. The composition of the different soils and of the rocks from which they were originally derived is given. All of the soils responded to applications of nitrogen. Their behavior toward potash was variable, depending upon their origin and content of available potash as shown by analysis. The basalt, shell lime, and clay slate soils were benefited by applications of phosphoric acid, the graywacke soils did not respond to such applications, and bunter-sandstein soils varied in their behavior toward phosphoric acid according to the amounts of available phosphoric acid present as shown by analysis. Only the basalt soils showed a need of lime. It was concluded that pot experiments are a reliable means of determining the fertilizer requirements of soils.

**The effect of plant growth and of manures upon the retention of bases by the soil.** A. D. HALL and N. H. J. MILLER (*Proc. Roy. Soc. [London], Ser. B, 77 (1905), No. B514, pp. 1-32, figs. 2; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 520, II, pp. 119, 120*).—The investigations reported in this article deal “with the changes in the amount of calcium carbonate, the chief substance in the soil acting as a base, which are brought about by natural agencies, by manuring, and particularly by the growth of plants.”

It is stated that the Rothamsted soils generally contain about 3 per cent of calcium carbonate, due mainly to former applications of chalk. “Determinations made in numerous samples from different plats of Broadbalk, Agdell, and Hoos fields, taken at different dates from 1856 to the present time, show that the soils of the unmanured plats lose in drainage on the average about 1,000 lbs. of calcium carbonate per acre per annum. This agrees closely with results derived from analyses of field drainage by Creydt, von Seelhorst, and Wilms [*E. S. R.*, 13, p. 723; 16, p. 856].

“The loss of calcium carbonate is increased when ammonium salts are employed by an amount equivalent to the acid of the manure. Sodium nitrate and farmyard manure diminish the loss.

“Analyses of wheat plants grown in water culture and of the solutions themselves showed that the plants take up an excess of acid from the salts supplied, leaving behind a corresponding excess of base. This explains how it is that, despite losses by nitrification, soils which contain only minute amounts of calcium carbonate (examples of such soils are given) are able to maintain a neutral condition. The experiments also furnished evidence that the roots of the plants did not excrete any organic acid or other organic matter.

“Finally it is shown that calcium oxalate and other organic salts are converted into carbonate by soil organisms.”

**Investigations on changes in the nitrogen of soils.** F. LOHNIS (*Mitt. Landw. Inst. Leipzig, 1905, No. 7, pp. 1-105; Zentrbl. Bakt. [etc.], 2. Abt., 15 (1905), Nos. 12, pp. 361-365; 13-14, pp. 430-435; abs. in Jour. Chem. Soc. [London], 88 (1905), No. 518, II, p. 854; 90 (1906), No. 519, II, p. 46*).—The investigations here reported were made on soil of a plat on the Oberholz experimental field of the agricultural institute of the University of Leipzig during 1903 and 1904.

Oats were grown on the plat in 1903, and after these were harvested half of the area was given shallow cultivation while the other was left in stubble. In 1904 the field was planted in potatoes, which received applications of the various fertilizers (bone meal, lime nitrogen, urea, ammonium sulphate, sodium nitrate, etc.), the transformations of which it was the purpose of the experiments to study, namely, the formation of ammonia from bone meal, lime nitrogen, and urea; the formation of nitrate from ammonium sulphate; the liberation of nitrogen from nitrate, and the fixation of nitrogen by bacteria. The influence of the time of year (temperature), weather, and of various methods of culture on the yields and utilization of the nitrogen of the different fertilizers was also studied, and the different kinds of bacteria which took part in the transformation of the nitrogen were isolated and determined.

Decomposition was least affected by the season of the year in case of bone meal and most in case of urea and calcium cyanamid. The nitrogen of calcium cyanamid was quickly converted into ammonia during April and May, and its effect on the crop was similar to that of ammonium salts. It was found that *Bacillus mycoides* converted 39 per cent and *Bacterium vulgare* 28 per cent of the total nitrogen of bone into ammonia in 3 weeks. Allowing the soil to remain in stubble had a distinct effect on denitrification and nitrogen assimilation, but not on the other changes.

The chief effect of bringing the lower layers of the soil to the surface was to diminish nitrification, the least effect being observed in the case of decomposition of bone meal and urea, while there was no effect as regards nitrogen assimilation and decomposition of calcium cyanamid. Dry weather in July was especially injurious as

regards nitrification, nitrogen assimilation, and the decomposition of calcium cyanamid, but was practically without effect on denitrification and decomposition of bone meal and urea. It is concluded that water to the extent of from 60 to 80 per cent of the water-holding capacity of the soil is required for the uninterrupted progress of the various changes in the nitrogen of the soil.

In these investigations soil extracts were used as a culture medium with good results. These extracts were prepared by boiling 1 kg. of soil for 2 hours with 2 liters of tap water. The solution, evaporated to a volume of about 800 cc., was cleared up with talc and filtered, and the filtrate was evaporated until it contained about 0.4 per cent of inorganic constituents. In this way 1 kg. of soil gave as a rule about 600 cc. of neutral extract containing 0.4 per cent of inorganic and 0.6 per cent of organic constituents. The nitrogen content was about 0.02 per cent and the solution was almost entirely free of phosphoric acid. Except in the case of the experiments with bone meal, therefore, about 0.5 per cent of dipotassium phosphate was added. In the experiments reported this extract was inoculated with soil, using the latter at the rate of 10 gm. of soil to 100 cc. of solution.

**Report of the chemical laboratory of the Ploti Agricultural Experiment Station, B. M. WELBEL** (*Ghodontnui Otchet Ploty. Selsk. Khoz. Opitn. Stantsii, 10 (1904), pp. 75-120; abstr. in Centbl. Agr. Chem., 35 (1906), No. 2, pp. 73-76*).—A continuation and extension of previous work (E. S. R., 16, p. 552) on atmospheric precipitation, lysimeter observations, and experiments in vegetation boxes is reported.

The report deals with studies of the adaptability of lysimeters to the investigation of questions relating to the balance of water and nitrogen in the soil as influenced by variations in precipitation, methods of culture, manuring, etc. Three groups of lysimeters installed at the station and the kind of investigations for which they are used are described. It has been found that the method of construction and of filling the lysimeters has a most important bearing upon the results obtained.

Special attention has been given in the experiments with the lysimeters to a comparison of the influence of black fallow and green fallow on the water and nitrogen content of the soil. Black fallow as practiced in these experiments consisted of cultivating the soil and allowing it to lie idle until the following fall. Green fallow consisted in allowing the land to lie without cultivation from one summer to the next. More water accumulated in the lower layers of the black fallow soil than in those of the green fallow, the reverse being true for the upper layers of the soil, but in the latter case the differences were very small.

The drainage was greater in case of the black fallow than in case of the green. There was a greater accumulation of nitrates and greater loss in drainage in the black fallow than in the green. The losses in the drainage were, however, more than made good by nitrogen compounds brought down from the air, aggregating 4.5 kg. of nitrogen per hectare annually. During three years of observation the application of barnyard manure increased the production of nitrates (nitric nitrogen) in the soil 120 kg. per hectare. During the same period soil bearing alfalfa produced 50.22 kg. of nitric nitrogen more per hectare than soil not bearing alfalfa.

**Some field notes on soil inoculation, H. N. STARNES** (*Georgia Sta. Bul. 71, pp. 91-105, pls. 12*).—The present status of knowledge regarding soil inoculation for legumes is briefly reviewed and experiments with commercial cultures of nitrogen-fixing bacteria on cowpeas grown in an isolated field of typical red-clay land in a low state of fertility are reported.

The experiments were made on fertilized and unfertilized areas of this soil. The results do not indicate any particular advantage from inoculation. "In yield of vines an increase appears per acre of 175 lbs., or about 3 per cent, in favor of the untreated over the inoculated plats, while in the yield of peas the difference is reversed, there being apparent an increase of 35 lbs. per acre, or something less than 5 per cent, in favor of the inoculated plats."

The conclusion is reached "(1) that few soils throughout middle Georgia are likely to be found not already thoroughly colonized or inoculated with the special form of *Pseudomonas radiculicola* which uses the cowpea as its host. (2) Consequently, whether the commercially distributed 'cotton-dried' nitro-culture for the cowpea does or does not contain living colonies of this bacterium, it is valueless here."

Observations on a series of introduced leguminous plants indicate that the cowpea organism, which is everywhere abundant in the soils of the station farm, is capable of inoculating leguminous plants of widely differing species. Among the unusual plants so tested and found to develop root tubercles when grown for the first time on the station farm were green gram (*Phaseolus viridissimus*), Newman bean (*P. mungo*), *P. radiatus*, *P. aconitifolius*, and *P. angustissimus*.

"Now, the bacteria forming these tubercles were derived either from the soil itself (that is, from the universally disseminated cowpea bacteria) or were conveyed by the planted seed. The latter hypothesis, though possible, is unlikely, especially since desiccation has been proven so extremely fatal to *P. radiculicola*. Had the seed been sterilized before planting it would have, of course, determined the matter; but the plat was merely a variety test of certain Phaseoli, with no reference to its bearing upon soil inoculation. In either case it seems to indicate that our soil is not dependent upon artificial inoculation."

**Soil inoculation for legumes from artificial cultures by the help of bacteria**, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 126, pp. 28-30).—Negative results in inoculation experiments with peas, clover, and alfalfa on a number of farms in different parts of Maine during the season of 1905 are reported. The cultures used for inoculation were obtained from this Department and from a commercial concern. The farmers of the State are cautioned not to depend upon such cultures, but in case of attempts to raise leguminous crops not commonly grown in the region to inoculate their land with soil from fields on which the crops have been grown.

**An experiment with Moore's cultures of nitrogen-fixing bacteria**, V. PAGLION (*Staz. Sper. Agr. Ital.*, 38 (1905), No. 9, pp. 769-784, pls. 4).—The results of experiments with medic, lupines, sulla, and white clover on virgin and cultivated soils indicate as a rule that Moore's cultures were very active in producing root tubercles and in increasing growth in soils which had not already been inoculated by natural means; but the writer points out that such conditions are exceptional in localities where legumes of various kinds have been grown for centuries, and hence the cultures have only a limited usefulness in practice and should not be expected to take the place to any extent of good cultivation and the application of mineral fertilizers to promote the growth of legumes.

**Nitrification of the organic matter applied to the soil in form of sewage**, G. MASONI (*Atti R. Acad. Econ. Agr. Georg. Firenze*, 5. ser., 2 (1905), No. 3, pp. 196-208).—This is an account of a continuation of previous experiments by the author and relates particularly to the relation of moisture to denitrification.

The experiments here briefly reported lead to the conclusion that liquid sewage from cesspools is not only capable of rapidly nitrifying when applied to the soil, but also aids nitrification in the soil itself. Loss of nitrogen from the soil during hot dry summer weather may be checked by applications of sewage.

**Recent experiments in the nitrogen-enrichment of soils**, F. T. SHUTR and A. T. CHARRON (*Separate from Proc. and Trans. Roy. Soc. Canada*, 2. ser., 11 (1905), Sec. III, pp. 53-64).—This paper (1) presents the results of certain recent researches that demonstrate the extent and rapidity of the depletion of soil nitrogen under what is evidently an irrational method of farming, and (2) brings forward data to show the value of the legumes, especially clover, as a means of maintaining and increasing fertility through the addition of nitrogen and humus. The discussion is based upon field and laboratory studies made by the authors at the Canadian Experimental Farms.

**A new nitrogenous manure**, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 18 (1906), pp. 75-77).—Field experiments on oats and barley with lime nitrogen as compared with nitrate of soda and sulphate of ammonia are briefly reported. The results show that the lime nitrogen was but slightly inferior to nitrate of soda or sulphate of ammonia. "In no case did any injury appear to be caused to the germination of oats or barley by using the cyanamid at the rate of 1 cwt. per acre along with the seed."

**The conversion of atmospheric nitrogen into nitric acid**, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 8, pp. 233-235).—This article briefly reviews investigations on this subject and describes the various methods which have been proposed for fixing the nitrogen of the air, particularly that of Birkeland and Eyde.

**Chemistry and the world's food**, R. K. DUNCAN (*Harper's Mo. Mag.*, 112 (1906), No. 671, pp. 720-731).—A popular review of progress in investigations relating to the utilization of the nitrogen of the air for industrial purposes, especially as a fertilizer.

**Nitrogen requirements of crops**, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 7, pp. 201-203).—The demands of crops on the nitrogen of the air and the soil are briefly discussed.

It is estimated that the crops produced on the 24,000,000 hectares (9,716,575 acres) of land under cultivation in France remove about 273,000 metric tons more of nitrogen, 149,000 tons more of phosphoric acid, and 377,000 tons more of potash than is returned to the soil by farm manures. The most economical means of making up this deficit are discussed.

**Fertilizers**, E. HASELHOFF (*Jahresber. Agr. Chem.*, 3. ser., 7 (1904), pp. 100-229).—A review is given of the literature relating to this subject published during 1904, classified as follows: Analyses of fertilizers and preservation of manure, results and methods of fertilizer control, and fertilizer experiments.

**Commercial fertilizers**, G. ROBERTS (*California Sta. Bul.* 171, pp. 29, figs. 3).—The results of fertilizer inspection during the year ended June 30, 1905, are reported, including analyses of 151 samples of fertilizers and notes on valuation, mechanical condition of fertilizers, etc., and the text of the fertilizer law.

**Commercial fertilizers**, G. ROBERTS (*California Sta. Bul.* 173, pp. 26).—This bulletin gives the results of fertilizer inspection during the six months ended December 31, 1905, including analyses of 138 samples of fertilizers and a list of brands of fertilizers and fertilizing materials offered for sale by the registered manufacturers and dealers in the State.

**Fertilizer inspection**, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 127, pp. 47-64).—This bulletin contains the analyses of manufacturers' samples of brands of fertilizers licensed before February, 1906, with explanations regarding constituents of fertilizers and valuation.

**Commercial fertilizers**, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 121, pp. 81-104).—This is the first bulletin issued in connection with the fertilizer inspection for 1906 and gives results of analyses of 56 brands. A table is also included showing the composition of 126 brands on sale in the State during the past 5 years. The character and contents of the more important previous bulletins of the station on fertilizers are explained and notes are given on valuation.

**Commercial fertilizers**, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul.* 97, pp. CIII-(VII+108-170).—This is the complete report of the work of fertilizer inspection in West Virginia during 1905, including analyses of 238 samples.

**Commercial fertilizers**, M. S. McDOWELL (*Ann. Rpt. Penn. Dept. Agr.*, 10 (1904), pp. 135-155).—This is a general discussion of the sources, nature, and uses of the various commercial supplies of nitrogen, phosphoric acid, and potash.

**Artificial fertilizers, their functions and use**, F. E. LEE (*Jour. Dept. Agr. Victoria*, 3 (1905), No. 10, pp. 713-725, fig. 1).—This article summarizes information

regarding the source, nature, and use of fertilizers, giving also suggestions regarding the mixing of fertilizers and a discussion of methods of valuation.

**The fertilizer industry** (*Tradesman*, 54 (1906), No. 9, pp. 98, 99).—Data are given for 10 southern States, showing 162 fertilizer establishments with an invested capital of \$29,966,685 and a value of product of \$18,921,591.

**Mineral resources of the United States, calendar year 1904**, D. T. DAY (*U. S. Geol. Survey*, 1905, pp. 1264, pls. 2).—The principal information of agricultural interest in this report has already been noted from another source (*E. S. R.*, 17, p. 451).

**Fertilizer trials at the Royal Agricultural Academy of Sweden, 1903-4**, H. G. SÖDERBAUM (*K. Landtbr. Akad. Handl. och Tidskr.*, 44 (1905), No. 4-5, pp. 289-311, fig. 1).—On the after effects of different kinds of phosphatic fertilizers.—This is a report of an investigation conducted since 1901, in which the effects of the following phosphatic materials have been studied: Superphosphate, dicalcium phosphate, tricalcium phosphate, precipitated phosphate, and bone meal. Different varieties of oats were grown in vegetation pots each year, and after the first year applications of sodium nitrate and potassium sulphate, with or without addition of calcium carbonate, were made each year.

The highest aggregate yields of oats for the four-year series were obtained from the applications of superphosphate and of dicalcium phosphate, and the action of these fertilizers appeared to be independent of whether or not lime had been added. The effect of both tricalcium phosphate and bone meal was reduced by nearly one-half during the four years by the addition of lime, and the superiority of the former over the latter in the case of the limed pots, and of bone meal over the tricalcium phosphate in the case of the pots receiving no lime, gradually disappeared, so that the total results for the entire series were practically the same. The action of bone meal (with no lime) was found to be decidedly inferior to superphosphate even after the fourth year.

*The fertilizer value of Algerian phosphate and apatite compared with that of other phosphatic materials.*—The trials were made in 10-in. glass cylinders, with oats grown in a sandy soil, and with peas grown in a marsh soil. In the former trials Algerian phosphate produced an increase of only 3.3 to 5.3 per cent over the cylinders receiving no phosphoric acid, the increase obtained in the case of superphosphate being placed at 100, and the increase in the case of the fine-ground apatite amounted to 0.4 to 1 per cent, according to the quantity of phosphoric acid added (50 to 150 kg. per hectare). In the latter trials with peas on marsh soil the effect of the sifted Algerian phosphate was about 57 per cent of that of superphosphate for peas alone, and 63.7 per cent for the entire crop (peas and vines). The corresponding figures obtained for apatite were 3.9 per cent and -1.4 per cent.

*Culture trials to determine in how far the effect of phosphatic fertilizers depends on the character of the simultaneous nitrogenous fertilization.*—It has been found in earlier investigations that the effect of superphosphate or dicalcium phosphate was not influenced by the kinds of nitrogenous fertilizer applied, but that the tricalcium phosphate and bone meal produced appreciably larger crops when mixed nitrogenous fertilizers were applied than when sodium nitrate only was added with the phosphates.

This subject was studied further by the author during the years 1902 to 1904. In pot experiments with Ligowo oats, in which different phosphatic materials were added with either nitrate of soda or nitrate of ammonia, the results obtained with superphosphate or Thomas phosphate were higher in the case of applications of nitrate of soda than when corresponding amounts of ammonium nitrate were applied, while the opposite held true with Algerian phosphate and with bone meal. The effect of applications of different nitrogenous fertilizers in connection with bone meal

was next studied, also for Ligowo oats, with the result that a marked increase in yields was obtained with ammonium sulphate.

The next highest results were secured in the case of fertilization with ammonium sulphate and sodium nitrate, while sodium nitrate alone with bone meal gave the lowest results, this effect being equally marked both in the yield of total crop and of grain. Liquid manure or albumen with sodium nitrate gave somewhat lower results than sodium nitrate and ammonium sulphate. The effect of the phosphatic fertilizers applied is, therefore, shown to depend to a large extent on the character of the nitrogenous fertilizers applied or present in the soil.

*Culture trials with nitrogenous and phosphatic fertilization in increasing amounts.*—These trials were planned to study the methods of pot experimentation. They were conducted in glass cylinders, 29 cm. deep by 24 cm. in diameter, filled with 28½ kg. of a sandy soil, low in nitrogen (0.011 per cent) and phosphoric acid (0.04 per cent phosphoric acid soluble in hot hydrochloric acid, sp. gr. 1.15), the crop grown being oats.

In the first series, in addition to a basic fertilization of fine-ground marble, superphosphate, and potassium sulphate, with a slight addition of magnesium sulphate and salt, sodium nitrate was added to different cylinders in amounts ranging from 1.5 to 6 gm. per cylinder (50 to 200 kg. per hectare). Increasing nitrogenous fertilizations in all cases produced an increase in the crops harvested, the increase being largest with the smallest amounts of nitrate applied and smallest with the heaviest applications, so that the increase obtained beyond applications of 150 kg. per hectare (134 lbs. per acre) may be considered within the limits of experimental error.

Both the weights of kernels and of straw increased with increasing applications of nitrate. The ratio of straw to kernels was narrowest in the case of the largest amounts applied, up to 125 kg. per hectare, when a small widening of the ratio began to appear. It was found, in general, that a fertilization of 150 kg. per hectare (= 0.026 gm. per kilogram of soil) produced an optimum development of the crop, and that the crop produced on a fertilization of 50 kg. of nitrate by its appearance gave decided evidence of a lack of proper nitrogenous fertilization.

In the second series the trials were conducted under similar conditions as in the case of the preceding series; 0.71 to 5.71 gm. of superphosphate (corresponding to 25 to 200 kg. per hectare) were added to sets of 3 cylinders each. The increase in the oat crop harvested from the different cylinders was less regular in this than in the preceding series. The highest increase was obtained between 25 and 50 kg.; between 75 and 125 kg. only a small increase in yield was secured, while at 150 kg. a marked increase again occurred, the maximum crop being obtained at 175 kg. Between 175 and 200 kg. a decrease in yield occurred. The optimum results evidently lay between 75 and 150 kg., and may be placed at 0.017 gm. per kilogram of soil for the soil experimented with and under the conditions of these trials.—F. W. WOLL.

**On the factors which influence the fertilizing value of the phosphoric acid of bone meal,** H. G. SÖDERBAUM (*Landw. Vers. Stat.*, 63 (1905), No. 3-4, pp. 247-262).—Experiments in glass cylinders 50 cm. high and 25 cm. in diameter carried out with oats during 1902 and 1903 are reported. (See also the preceding abstract.) They included comparative tests of superphosphate, dicalcium phosphate, tricalcium phosphate, Thomas slag, Algerian phosphate, apatite, and bone meal alone or combined in various ways with sodium nitrate, ammonium nitrate, ammonium sulphate, and other nitrogenous fertilizers (some organic), the object of the combination being to determine the influence of the different nitrogen compounds on the availability of the phosphoric acid of the phosphates, as has also been done by Priianishnikov (*E. S. R.*, 17, p. 538).

The results show that the bone meal in presence of ammonium salts, as well as of organic nitrogen compounds, gave larger yields than when used in connection with

nitrate of soda alone. Similar results were obtained with Algerian phosphate and precipitated tricalcium phosphate. An increase of yield was produced by mixtures of nitrates and ammonium salts as well as by ammonium salts alone, the maximum increase occurring in case of the latter. The yield of grain was, as a rule, increased more than that of straw, the greatest increase of straw being, as a rule, with applications of organic nitrogen compounds. The increase due to applications of ammonium salts varied widely from year to year with the weather conditions.

Under favorable conditions the total yield was more than doubled, the yield of grain nearly tripled by the bone meal. In case of superphosphate, Thomas slag, and precipitated dicalcium phosphate there was no such increase of yield following the application of ammonium salts. In fact, in some cases there was a decided decrease in yield. When lime was not present in large amounts the bone meal in combination with ammonium salts was fully as effective as superphosphate.

**Methods of using untreated rock phosphate**, E. T. MEHARRY (*Ill. Agr.*, 10 (1906), No. 5, pp. 173-177).—This is a summary of experiments by the Maryland, Ohio, and Illinois stations on the fertilizing value of untreated rock phosphate.

**Manurial value of molasses residue as compared with ammonium sulphate and 40 per cent potassium salts**, LILIENTHAL (*Illus. Landw. Ztg.*, 25 (1905), No. 34, pp. 319, 320; *abs. in Jour. Chem. Soc. [London]*, 88 (1905), No. 516, II, p. 650).—The dried molasses residue used in the comparative tests here reported contained 3.5 per cent of nitrogen and 13 per cent of potash, but no phosphoric acid. The residue produced about the same yield of potatoes as the mixture of ammonium sulphate and 40 per cent potash salt, with which it was compared. The quality of the potatoes produced was good.

**The development of the potash industry**, H. PRECHT (*Ztschr. Angew. Chem.*, 19 (1906), No. 1, pp. 1-7).—A brief review of the history and present status of this industry.

**German potassium deposits**, W. SCHMIDTMANN (*Amer. Fert.*, 23 (1905), No. 6, pp. 22-24).—A brief explanation of the formation of these deposits is given, and a doubt is expressed as to whether like deposits of equal strength and purity exist in any other country.

**The use of lime in agriculture**, D. A. GILCHRIST (*Jour. Bd. Agr. [London]*, 12 (1905), No. 7, pp. 400-406; *Trinidad Bot. Dept. Bul. Misc. Inform.*, 1906, No. 49, pp. 18-22).—A summary of available information regarding sources of supply, methods of application, and action of lime in the soil, considered mainly from the British standpoint.

**Corncocks as fertilizers and as fuel** (*Industrialist*, 32 (1906), No. 17, pp. 270, 271).—Compiled analyses are reported to show that corncocks have very little value as fertilizer (2 lbs. of nitrogen, 0.4 lb. of phosphoric acid, and 6.8 lbs. of potash, worth \$1.36) and less than that of barnyard manure, wheat straw, or corn stalks. They are of more value as fuel (\$2 per ton if wood is worth \$6), and the resulting ashes are rich in potash (about 50 per cent). The feeding of charred coles to poultry and hogs for tonic or medicinal purposes is recommended.

**Dead leaves as a fertilizer** (*Mo. Consular and Trade Rpts. [U. S.]*, 1905, No. 303, p. 276).—A brief note is given on a report from the U. S. consul at Nantes on the relative fertilizing value of the leaves of different trees. From the results reported it is concluded that 44 lbs. of pear leaves, 80 lbs. of poplar, 51 lbs. of peach, 83 lbs. of locust, 82 lbs. of elm, and 174 lbs. of vine, respectively, are equal in nitrogen to 100 lbs. of ordinary manure.

**Hog bristles as a fertilizer**, E. MIEGE (*Jour. Agr. Prat., n. ser.*, 11 (1906), No. 5, p. 145).—This material contains about 9 per cent of nitrogen, which is very slowly available in the soil. The improvement of its availability by treatment with superheated steam, acids, etc., or by composting, is suggested. It is stated that gardeners have used the material with success for destroying slugs.

**Bat guano from the Federated Malay States, W. R. DUNSTAN** (*Agr. Bul. Straits and Fed. Malay States*, 4 (1905), No. 10, pp. 394-397).—Descriptions and analyses are given of 4 samples of bat guano obtained from caves in different parts of the Malay States. The results show that although these guanos are comparatively rich in phosphoric acid (8.6 to 17.52 per cent), of which a fairly large proportion (3.25 to 9.75 per cent) is soluble in ammonium citrate solution and is therefore in condition to be readily utilized by plants, they are deficient in the very important constituents, potash (0.88 to 2.01 per cent) and nitrogen (0.84 to 2.47 per cent).

**Water as a plant food, BACKHAUS** (*Chem. Ztg.*, 29 (1905), No. 80, p. 1067; *Fühling's Landw. Ztg.*, 54 (1905), No. 22, pp. 757-762).—Observations made on the Berlin sewage farm during the dry season of 1904 on the value of water as a factor of production are briefly reported, and the actual money value of the increase due to the application of 1 cubic meter of water in case of oats, wheat, hemp, and grasses is calculated. The latter varied from 1.35 cts. in the case of grass to 2.57 cts. in the case of oats.

The conditions necessary to the fullest and most economical use of water in plant production are also discussed, including increasing rainfall by forest planting, storage of water and construction of other irrigation works, deep culture, increasing humus content of the soil, controlling the water content and evaporation, choice of cultivated plants, tillage, etc.

## FIELD CROPS.

**The breeding of agricultural plants, C. FRUWIRTH** (*Die Züchtung der landwirtschaftlichen Kulturpflanzen. Berlin: Paul Parey, 1905, pp. XVI + 201, figs. 25*).—Previous volumes of this work have already been noted (*E. S. R.*, 16, p. 1065). This volume, the third of the series, treats of breeding potatoes, Jerusalem artichokes, flax, hemp, tobacco, hops, and leguminous forage plants, including clovers. Thirty different species are discussed and notes on the blossoming period, pollination, selection, correlation, variation, hybridization, and seed culture are given. A bibliography of 54 references, including books, bulletins, and periodicals, is listed.

**Report of work at McNeill Branch Experiment Station for 1904, E. B. FERRIS** (*Mississippi Sta. Bul.* 87, pp. 7-16).—In a corn fertilizer test the same quantities of nitrogen and phosphoric acid gave practically the same yields when given as cotton-seed meal and acid phosphate, cotton-seed meal and reverted acid phosphate, or raw ground bone. The cotton-seed meal was applied at the rate of 84 lbs., the acid phosphate 232 lbs., the reverted acid phosphate 414 lbs., and the raw ground bone 166 lbs. per acre. In a variety test with corn, Cocks Prolific and Eureka headed the list with yields of 51.6 and 51.5 bu. per acre, respectively.

In a fertilizer test with cotton 126 lbs. per acre each of acid phosphate and cotton-seed meal gave 700 lbs. of seed cotton; 165 lbs. of ground bone, 780 lbs. of cotton; and 168 lbs. of cotton-seed meal and 70 lbs. of acid phosphate, 710 lbs. of cotton per acre. Nearly all other applications gave much lower yields. Among the different varieties tested Allen Long Staple stood first in the production of seed cotton. The average of plats with the rows 4 ft. apart gave 742 lbs. of seed cotton per acre, which was considerably better than was obtained from narrower plantings.

Cowpeas grown as a second crop matured after the rainy season was over and made good hay. It is stated that peas planted early in the season have very little tendency to make fruit, while those planted the latter part of June or in July are likely to fruit heavily. A large and profitable crop of sweet potatoes was grown, the leading variety being Dooley Yam.

In work with sugar cane 420 gal. of first-class sirup was secured on one-half acre of plant cane. Immature tops of cane and tops with only one mature joint were used for planting, but were found unsatisfactory. It is estimated that the yield of

cassava roots secured at the station was at the rate of 15,000 lbs. per acre. Few crops are believed to equal it in tonnage on the sandy soils on which it was tested.

Deep preparation for corn, with shallow cultivation, gave better results than other methods of treatment, while with cotton deep preparation and deep cultivation gave practically the same yield as deep preparation and shallow cultivation. The deep preparation of the land consisted of subsoiling to a depth of 18 in. during the spring of 1903 and plowed to a depth of 5 in. during the spring of 1904, while for shallow preparation the ground was broken 5 in. deep during both seasons.

An inoculated plat of vetch grew to be waist high and was very strong and vigorous, while an uninoculated plat gave very poor results. Notes are also given on rape and Bermuda grass which were grown at the station.

**Report of field work done at the [Mississippi] station for 1904, W. R. PERKINS (*Mississippi Sta. Bul. 38, pp. 13*).**—Among 10 varieties of short staple cotton the highest total value per acre, \$49.02, was produced by Cook Improved. The production of the least remunerative variety, Berry Big Boll, was equal in value to \$26.59. John Bull, a long staple cotton, and Cook Long Staple produced values equal to \$52.78 and \$52 per acre, respectively. It is pointed out that the growing of long staple cotton is not always the most profitable. The different varieties here tested are briefly described.

Ten varieties of corn were tested and among them Hick Improved Marlboro stood first with a yield of 55.8 bu. per acre, followed by Columbian White Mammoth with 52.3 bu. The yields of soy bean hay from 4 varieties ranged from 3,880 to 6,148 lbs. per acre. Yields of Johnson grass hay on 3 different plats varied from 3.75 tons per acre to 5.91 tons. From an average fertilizer application of 87½ lbs. of cotton-seed meal and 100 lbs. of nitrate of soda a profit of \$4.93 per acre was secured in growing Johnson grass hay. The experience of the station in growing alfalfa has been that crab grass is likely to kill out the alfalfa plants.

The comparative value of oats, cowpeas, and corn for the production of forage was studied. The value of corn fodder per acre amounted to \$14.14, of cowpea hay to \$14.63, and of oats and cowpea hay to \$16.11.

**Report on field crops at the Sugar Experiment Station, Audubon Park, New Orleans (*Louisiana Stas. Rpt. 1905, pp. 3-9, figs. 2*).**—It is reported that seedling canes D. 74 and D. 95 have maintained the high standard of previous years. This season D. 74 tasseled in several places in the State as well as in Florida, and it is hoped that seedlings originating in Louisiana may be produced. Promising results secured in tests with cane loaders and harvesters are reported, and it is stated in this connection that D. 74, standing erect and withstanding storms far better than the native canes, presents less difficulty to harvesting with machinery.

Among notes on various crops grown at the station it is reported that maximum yields of 3,162 lbs. of seed cotton and 3,140 lbs. of cured alfalfa hay per acre were secured.

**Cereal investigations (*Kansas Sta. Rpt. 1905, pp. 20-26*).**—A description is given of cooperative experiments with the Bureau of Plant Industry of this Department in the testing of newly introduced varieties, and of hybrids and selections of cereal crops.

The work is carried on at McPherson and Fort Hays. Many of the results secured have already been noted (*E. S. R., 17, p. 129*). The yields of the different varieties of cereal crops grown in 1904 are tabulated and the extent of the plantings for 1905 is outlined. The weather conditions and the growth of the various crops during the season are discussed and the rainfall for the year beginning July 1, 1904, is recorded.

**The prevention of lodging in cereals (*Rev. Gén. Agron., 15 (1906), No. 1, pp. 18-21*).**—The lodging of cereals is discussed and a method of preventing it described.

It was found that on very rich soil by mowing luxuriantly growing grain when 30

cm. high, removing the upper 15 cm., and leaving the cut material as it falls will not only prevent lodging but will also make a more uniform crop in length of straw and size of head and kernel. If after the first cutting the growth of the crop is vigorous enough to indicate danger of lodging, it may be cut again about 2 weeks later when the plants have again reached the height of 30 cm. The mowing should be done when the dew is off, preferably in the afternoon. This method was successfully applied in 1901 on Chevalier barley growing on rich and well-fertilized soil during a warm, rainy season.

**Prout's farm, an example of 45 years' continuous culture of cereals without manure, B. SKALWEIT** (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 8, Sup. 3, pp. 15-16).—The general management of the farm, the crop rotations followed, the use of commercial fertilizers, the cost of production, and the value of the crops produced are briefly discussed.

**Report on experiments carried out at Bramford and Saxmundham by the East Suffolk Education Committee, T. H. MIDDLETON** (*Cambridge Univ., Dept. Agr.*, 1904, pp. 48, dgm. 1).—A rotation experiment was conducted to study the effects of different kinds of plant food on common crops. The crops grown in the rotation were roots, barley, clover or beans, and wheat. The fertilizers used were nitrate of soda, superphosphate of lime, and muriate of potash.

The importance and value of these three fertilizers varied with the soil and the crop. On clay soil nitrate of soda was of great value to mangels and of some value to barley; superphosphate, to clover, mangels, and barley, while potash had little or no effect. On light soil nitrate of soda benefited mangels and barley, and muriate of potash mangels and clover; but superphosphate did not benefit any of the crops. The continuous use for 12 years of 2 cwt. of nitrate of soda per acre on the light soil did not deteriorate the land, while a similar use of superphosphate was injurious to mangels and apparently, to a slight extent, to some of the other crops. The continued use of barnyard manure for 12 years on this light soil did not result in any appreciable accumulation of fertility.

In the second rotation experiment the quantities of manures to be used, the time of their application, and their effect were studied. The best results were secured by using 1 cwt. of nitrate of soda and 5 cwt. of superphosphate of lime per acre for the root crop, 2½ cwt. of superphosphate for barley, the same quantity the following season for clover, and 10 tons of barnyard manure for the wheat crop. The experiment further showed that residues of fertilizer applications may have substantial values, varying, however, with the crop. Clover extracted more from residues than barley and barley more than roots. It was shown that clover may receive great benefit from superphosphate applied a year before the crop is sown, while mangels appear to be benefited very little by the same treatment. It was also shown that the residue of any particular application is greatly influenced by the soil. The barnyard manure left a valuable residue on the clay soil and but an unimportant one on the light soil.

The results of experiments on the improvement of poor grass land show that on a clay soil from 5 to 10 cwt. of basic slag per acre is the most profitable application. Potash and lime did not prove profitable. The use of nitrogenous manures in conjunction with phosphates when beginning to improve poor clay soils is not recommended.

A fertilizer experiment with alfalfa showed that on clay soils this crop responds freely to phosphatic manures, remaining indifferent to dressings containing potash, while on sandy soils the potash manures are very effective and phosphates may fail to show improvement.

**Variety tests of wheat, oats, and potatoes, G. C. WATSON and N. G. MILLER** (*Pennsylvania Sta. Bul.* 76, pp. 13).—The yields of varieties most productive at the station since 1887 are reported.

Of 20 varieties of winter wheat 9 yielded over 31 bushels per acre. The 3 leading varieties, Harvest King, Martin Amber, and Royal Red Clawson, yielded 34.60, 34.58, and 34.22 bu., respectively. The average yield of all varieties was 29.17 bu. per acre. The average of the 13 smooth varieties was 28.86 bu., and that of the 7 bearded varieties 29.74 bu. Dietz Longberry Red and Reliable gave the heaviest weight of grain per bushel, 61.25 lbs. Of the varieties tested for 15 years Fulcaster stands in the lead with 31.13 bu. of grain and 3,821 lbs. of straw per acre.

The 19 varieties of oats grown in 1905 gave an average yield of 56.09 bu. per acre, the range being from 47.80 to 61.50 bu. Czar of Russia ranked first in the production of grain, and Mortgage Lifter, which stood last in grain production, ranked first in yield of straw. In 1904 White Russian was the leading variety, with 77 bu. of grain per acre, while Czar of Russia yielded only 69.13 bu. The yield of White Russian in 1905 was 56.93 bu. per acre.

Forty-three varieties of potatoes were grown this season and an average yield of 187 bu. per acre was secured, but of this quantity 27.4 bu. were unmerchantable tubers. The leading varieties, mentioned in decreasing order of yield, were Eureka, Heath Medium Late Beauty, Uncle Sam, Early Rose, Early Puritan, Extra Early Crusader, Irish Daisy, Early Nancy, and Bliss Triumph, all producing over 200 bu. of merchantable tubers per acre, while the remaining varieties fell below this yield. The average total yield for all the varieties for 1904 was 77.9 bu. more than the yield for 1905.

**Crops of southern France, Algeria, and Tunis.** C. RIVIÈRE and H. LECQ (*Cultures du midi de l'Algérie et de la Tunisie. Paris: J. B. Baillière & Son, 1906, pp. XII + 511, figs. 69*).—This book discusses the culture of tropical and subtropical crops grown in southern France and in northern Africa. The topics discussed are climate, cereal and garden crops, viticulture, forage crops, forestry, fruits, ornamentals, plants furnishing rubber, tannin, dyes, fibers, perfume, starch, oil, etc., and the marketing of fruits and legumes.

**Clark method of growing grass for hay.** C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126, pp. 25-28*).—About 2 acres of land was treated as nearly as possible in accordance with the Clark method.

The results indicated the value of thorough preparation of the seed bed and liberal applications of fertilizer in grass growing. The grass was sown in the fall of 1904 and in July of the next year 6½ tons of field-cured hay was harvested. This crop cost about \$40 for fertilizers and about \$37 for labor and seed. The station does not believe this method adapted to Maine, as it does not fit in with mixed farming and rotation of crops, and further, because the seeding formula recommended does not contain clover.

**Report on an experiment conducted at Cransley, Northamptonshire, in seasons 1901, 1902, and 1903: The improvement of poor pastures.** T. H. MIDDLETON (*Cambridge Univ., Dept. Agr., 1904, pp. 35, dgm. 2*).—The results of cooperative work indicated that to improve poor pastures on clay soils it is advisable to begin with the use of from 7 to 10 cwt. of basic slag per acre. Barnyard manure, sulphate of ammonia, or dissolved bone should not be used in the beginning, but may be applied after the first few years are over. The improvement of soil by clovers and the management of pastures is discussed.

**Range improvement.** J. J. THORNER (*Arizona Sta. Rpt. 1905, pp. 17-21*).—The range improvement work of the station for the year ending June 30, 1905, with the weather conditions for the period, is briefly reviewed.

A good growth of forage plants on the range reserve is reported, and the prevailing species are enumerated. Two common species of Indian wheat made the best growth, the average height being 10 in. In estimating the relative amount of spring forage on the mesas on small plats from which the plants were pulled up by the roots, dried, and weighed, it was found that the average yield was at the rate of 2,812 lbs. of forage to the acre.

Notes are given on cultural operations, the continuation of work upon the economic cacti, the forage garden, and on the viability of native grass seeds. The different species of forage plants sown on the range reserve and the percentage of germination as determined for a large number of native grasses are enumerated.

**Alfalfa**, T. F. HUNT ET AL. (*New York Cornell Sta. Bul. 237*, pp. 139-177, figs. 10).—This bulletin is a report of progress on cooperative tests with alfalfa in several parts of the State and of field tests on the college farm. An outline of cooperative demonstrations in the different branches of agriculture to be made in 1906 is appended.

The location and description of soils suited to alfalfa culture in the State are given, and the results of experiments with the crop are discussed. In 63 per cent of the cooperative tests in districts where alfalfa growing is not yet established no nodules at all were found on the plants. During 2 seasons' work with alfalfa bacteria transported by the cotton method, only one case gave an increase of vigor in the plants, while the method of inoculating by the use of soil from an old alfalfa field uniformly resulted in an abundance of nodules.

Dressings of lime usually proved beneficial, and on the heavier soil of the college farm it was found essential to the crop. The use of 2,000 lbs. per acre produced somewhat better results than 1,000 lbs. and practically as good as 3,000 lbs. The results on the heavy soils indicated that the best success is to be obtained by a combination of lime, stable manure, and inoculation by means of soil from an old alfalfa field. On gravelly loam soil alfalfa without a nurse crop grew much stronger before winter set in than that grown with a nurse crop, but this superiority was not maintained in the season's production. During 3 months' storage thoroughly field-cured alfalfa hay lost between 15 and 16 per cent in weight.

**Cooperative experiments with alfalfa**, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126*, pp. 35-41).—Cooperative culture tests with alfalfa in 1904-5 are described and directions given for the culture of the crop. The results thus far secured do not show conclusively that in general alfalfa can be successfully grown in Maine.

**Alfalfa and red clover**, J. W. WILSON and H. G. SKINNER (*South Dakota Sta. Bul. 94*, pp. 16, fig. 1).—The results of 3 years' experiments with alfalfa and clover at the station and in the forage tests at Highmore are presented.

In the spring of 1904 native sod on the college farm was disked 5 times and part sowed to alfalfa and part to clover, but only the clover made a fair stand. At Highmore a field of Turkestan alfalfa sowed in 1899 still produces good yields. Satisfactory results have been obtained with both the Turkestan and the American varieties. In 1902 a field foul with mustard was sown to alfalfa, with the result that the following year the mustard was practically killed out and a first-class stand of alfalfa was secured.

At the station Turkestan alfalfa sowed May 10, 1903, yielded 5,437 lbs. of hay per acre from 2 cuttings in 1904 and 5,113 lbs. from 2 cuttings in 1905. Montana-grown seed sowed in May, 1903, gave a total yield from 2 cuttings of 5,733 lbs. the following season. The experience in alfalfa culture by farmers throughout the State is briefly noted.

Clover was successfully grown on thoroughly disked native prairie and *Bromus inermis* sod. The seed was sown at the rate of 10 to 12 lbs. per acre and perfect stands were secured. A clover field 1 year old gave a total yield of 5,484 lbs. of hay per acre as compared with 3,294 lbs. on a sod-bound *Bromus inermis* field. In another field a total yield of 9,358 lbs. of hay per acre was secured from clover and only 2,360 lbs. from *Bromus inermis*.

**Culture of the fodder beet in Tunis**, R. GAGEY (*Bul. Dir. Agr. et Com. [Tunis]*, 9 (1905), No. 37, pp. 554-560).—The results of culture experiments with fodder beets are shown in tables.

In selecting a variety or choosing the distance between plants it is recommended that the total quantity of dry matter produced per hectare be taken into account and

not only the percentage. It was found that subsoiling for fodder beets increases the average weight and size of the roots, gives much larger total yields, and decreases the density and the percentage of dry matter, the beets being larger and containing more water. Although the percentage of dry matter is lowered, the total yield is generally increased, especially in dry years. A considerable increase in yield of beets was also secured by irrigation.

**Corn culture**, R. J. REDDING (*Georgia Sta. Bul.* 69, pp. 41-60).—Twenty varieties of corn tested in 1905 gave an average yield of 38 bu. per acre. The leading varieties, Albemarle and Marlboro, yielded 47.36 and 46.20 bu. per acre, respectively.

Residual effects of fertilizers applied to cotton in 1904 were not apparent in the corn crop of 1905. The plants fertilized this year yielded an average of 30.24 bu. and those not fertilized since 1904, 25.82 bu. per acre. This increase of 4.44 bu. from the use of fertilizers was secured at a cost of 80 cts. per bushel. A second fertilizer test gave similar results and it is concluded that the use of commercial fertilizers is not a reliable means to permanently increase the productiveness of soils.

Applying one-half of the quantity of cotton-seed meal at planting and one-half on May 19 was found inexpedient. Substituting the equivalent in nitrate of soda for one-half the quantity of cotton-seed meal did not prove profitable. As in previous years, cotton-seed meal was more effective than cotton seed applied directly to corn.

**Corn improvement**, J. A. JEFFERY (*Michigan Sta. Spec. Bul.* 34, pp. 23, figs. 15).—This bulletin is a popular discussion on the improvement of corn by a more careful selection of seed and better cultivation. Directions are given for the selection, storing, and testing of seed corn, and the different cultural operations connected with growing the corn crop. Cross breeding corn for the improvement of quality and the fixation of character are discussed and outlines for judging or scoring corn are given.

**Experiment with corn**, G. A. CROSTHWAIT (*Idaho Sta. Rpt.* 1905, pp. 33-35) -- In 1904 26 varieties secured from various sources were tested and the earliest ears selected for seed. Seed was saved from 9 dent and 2 flint varieties. Only a few ears were secured from each variety making seed, and 5 of those saved were from seed grown near Moscow. In 1905 over 50 varieties were tested and seed selection was made with reference to earliness.

**The germination of seed corn**, J. W. T. DUVEL (*U. S. Dept. Agr., Farmers' Bul.* 253, pp. 16, figs. 4).—The value of making germination tests is pointed out and complete directions for carrying on the work are given. Percentages of germination of seed corn as determined in individual ear tests of 10 kernels each from the crop of 1905 are shown in tables.

Of 67 lots of corn secured from various sources in different States 60 showed an average germination of less than 95 per cent, 48 of less than 90 per cent, and 10 of less than 80 per cent. The average germination of all ears tested was 86.3 per cent. The poorest lot contained only 2 good ears in 50, with 16 dead ears and an average germination of 39.4 per cent. The best 2 lots germinated 97.8 and 97.3 per cent, respectively, the first lot having 41 good ears in 50 and the second 42 in a possible 49. Of the 3,322 ears tested 1,416 germinated 100 per cent. The average germination of the remaining 1906 ears was only 77.7 per cent. This shows a gain of 13.7 per cent by discarding ears of low vitality.

**Experiments with cotton and corn in 1905**, J. F. DUGGAR and J. M. RICHESON (*Alabama Canebrake Sta. Bul.* 23, pp. 29).—Among the varieties of cotton grown, Russell and Woodfin gave the largest yields on bottom lands and Woodfin and Peterkin on poor upland. On bottom land Russell produced a crop valued at \$55.56 per acre for lint and seed. On poor red upland the value of the crop of Woodfin, the leading variety, was \$18.31 per acre in lint and seed, with lint at 11 cts. per pound and seed at 70 cts. per 100 lbs. Subsoiling for cotton which was done when the subsoil was too wet gave unfavorable results. In 2 tests plowing 6½ in. deep resulted in the largest crop, but in 2 other tests no advantage from deep plowing was derived.

The yields of corn were but slightly affected by the method of preparing the soil or planting the crop. Plowing under Egyptian clover and subsequently a crop of cowpeas increased the succeeding corn crop 9 bu. per acre. Corn stover, cotton-seed hulls, or tasseling corn plants plowed under showed no very marked advantage, but the benefits from successive applications of cotton-seed hulls and corn stover became greater each year. Tests made on prairie soils showed that vegetable matter rich in nitrogen, such as is afforded by barnyard manure, sweet clover, and cowpeas, is needed for their improvement.

On poor reddish prairie soils both acid phosphate and cotton-seed meal increased the yield of cotton quite profitably, the increase being 66 lbs. of lint per acre with the phosphate and 40 lbs. of lint with the cotton-seed meal. Kainit was found useless in this fertilizer experiment with cotton. Nitrate of soda, cotton seed, cotton-seed meal, and cow manure, at the rate of 44, 434, 100, and 2,704 lbs. per acre, respectively, used separately, were found profitable for cotton on all grades of prairie land. Acid phosphate did not give decisive results on black slough land but on poor reddish prairie soil this substance and slag phosphate were both found highly profitable. On gray prairie land in good condition the use of 800 lbs. of a complete home-mixed fertilizer, or 8 to 10 tons of barnyard manure gave good returns. Acid phosphate and cotton-seed meal were both more effective when applied before planting. The nitrate of soda gave good results when applied at the first or second cultivation of cotton. Manure from cattle fed on cotton-seed meal and hulls, applied in a small amount in the drill in both cotton and corn culture, increased the yield for each ton of manure about 18 per cent in the first crop after the application, 15 per cent in the second, and 9 per cent in the third, the increase aggregating in value in the 3 years from \$1.47 to \$11.94 per ton of manure.

Fertilizer applications for cotton and oats are suggested.

**Cotton culture**, R. J. REDDING (*Georgia Sta. Bul. 70*, pp. 61-90).—This bulletin is the report for 1905 on cotton experiments in progress at the station (E. S. R., 16, p. 866).

In the variety test of this year Cook Improved, which ranked first among 30 varieties in total value of crop produced, also stood first in earliness. The value of lint and seed produced by the different sorts ranged from \$44.68 to \$66.11 per acre. Cook Improved produced 533 lbs. of lint per acre and 880 lbs. of seed, and the next ranking variety, Brown No. 1, yielded 488 lbs. of lint and 767 lbs. of seed. These two sorts were followed by Layton Improved, Moss Improved, Southern Wonder, and Toole Improved, mentioned in the decreasing order of total value produced, and all yielding over \$57 worth per acre of lint and seed. The average height of the varieties grown was 3.67 ft., the range being from 3.23 ft. for Jones Re-Improved to 4.18 ft. for Lewis Prize. Moss Improved was the latest maturing variety. The best half of the varieties tested showed a tendency to produce a higher percentage of lint, a somewhat heavier boll, smaller seeds, and earlier maturing plants than the less productive half.

The results of 3 years' fertilizer experiments indicate that when nitrogen is given in the form of cotton-seed meal the best yields are obtained by making the entire application before planting. Such an application bedded on about 2 weeks previous to planting was found to induce early fruiting. From 16 to 20 lbs. of nitrate of soda per acre, applied in the furrow with the seed, has given good returns at the station. Substituting for one-half the quantity of cotton-seed meal its equivalent in nitrate of soda and applying the same as late as June 26 proved profitable. In the experience of the station growing cotton and corn simultaneously on the same ground can not be recommended.

The Mallory plan of preparing land for cotton showed no advantages over the ordinary method. The Mallory plan consists in throwing furrows 8 in. deep at half the distance apart of the intended cotton rows, and running deep subsoil furrows

within the furrows so made. This is done in the fall and the following spring alternate furrows are reopened with a shovel plow and the planting and application of fertilizers performed in the usual way.

A comparison of Peruvian guanos with home mixtures for cotton indicated that the same amounts of available phosphoric acid, nitrogen, and potash in the guanos were of equal value with the same elements in the forms of acid phosphate, cotton-seed meal, and muriate of potash. The results of an experiment with cotton-seed meal and crushed cotton seed, indicated that for fertilizing cotton 865 lbs. of cotton-seed meal is the fertilizing equivalent of 2,000 lbs. of crushed cotton seed.

Suggestions and formulas for the use of fertilizers in cotton culture are appended.

**Cotton in Egypt**, H. Lecomte (*Le coton en Égypte*. Paris: A. Challamel, 1905, pp. 162, figs. 28, map 1).—In discussing the present condition of the cotton industry of Egypt, this book devotes a chapter each to general cotton statistics, the soil, climate, varieties, variations, cultural operations, harvesting and ginning, soil exhaustion and fertilization, the distribution of cotton culture in Egypt together with the production and exportation of the country, and the culture of the crop in the Nile region under irrigation.

**Hardy Bermuda grass**, J. Fields (*Oklahoma Sta. Bul. 70*, pp. 8).—Experiments at the station have shown that Bermuda grass should be propagated only from the roots and pieces of sod of a sort that has survived severe winters in Oklahoma. The hardy strain growing at the station and elsewhere in Oklahoma quite generally survived the winter of 1905-6. Directions for planting Bermuda sod and its care after planting are given.

Two and one-half acres of thin upland soil were set to Bermuda grass on June 29 and 30, 1905, by sod planting, and on September 25 a yield of 2,584 lbs. of cured hay per acre, free from weeds and crab grass, was secured. The rainfall during this period amounted to 14.13 in. as compared with an average precipitation of 9.62 in. for the same period in previous years. An analysis of this hay made by the station chemist showed that it contained 9.70 per cent of protein and 1.24 per cent of fat.

**The preservation and storage of hops**, K. von Baur-Breitenfeld (*Pure Products*, 2 (1906), No. 3, pp. 145-150).—Investigations on the storing of hops indicated that hops should be stored in the hop chambers only when perfectly dry and ripe for bagging, and that sulphuring maintains the quality during storage.

The storage rooms should be kept at an even low temperature and perfectly dry. Temperatures from zero to 2 or 3° R. preserve hops better than higher temperatures because they reduce the moisture in the air to a greater extent and retard the oxidation of the hop resin and oil. The lower temperatures also better preserve the flavor of the hops. Hop chambers with direct refrigeration and stagnant air are as effective as those cooled by circulating cold air.

**The potato crop**, T. H. Middleton (*Cambridge Univ., Dept. Agr. Farmers' Bul. 3*, pp. 54).—Variety tests were conducted in 1903 and 1904 on a light loam soil. The best yields were secured from Dobbie Factor and Findlay Royal Kidney. Sutton Discovery and Findlay Evergood proved the most resistant to disease.

The sprouting of seeds before planting did not appear very useful for ordinary purposes. Planting entire tubers gave better results than the use of cut seed pieces. Tubers weighing 9 or 10 to the pound, or 1½ to 1¾ in. in size, were most suitable for planting. Seed imported from Scotland produced equally good crops the first and second years, while the third year the crop was much reduced. The second growth induced by weather conditions in 1904 had a very injurious effect on the cooking quality of the potatoes.

The best results on poor light land were secured with a fertilizer application consisting of 1½ cwt. of sulphate of ammonia, 3½ cwt. of superphosphate, and 1½ cwt. of sulphate of potash. On a light loam soil the best yield was secured where this same application of commercial fertilizers, together with 12 tons of barnyard manure per acre, was used. The barnyard manure alone also gave good results.

**Report on experiments with potatoes, 1905, W. BRUCE and J. PORTER** (*Edinb. and East of Scot. Col. Agr. Bul. 9, pp. 25, dgm. 1*).—Among 13 varieties of potatoes tested the second time Factor, Pink Blossom, and Up-to-Date were the only ones which yielded a heavy crop of fair quality. Of the medium early varieties King Edward VII was the most productive, being followed by White Blossom and British Queen. Some of the old standard varieties proved of equal value with the best of the new ones.

Sprouting the seed potatoes in boxes before planting increased the yield as well as the size of the tubers. Sprouted seed planted May 5 produced a better crop than unsprouted seed planted April 14.

On sandy soil the use of commercial fertilizers with barnyard manure was profitable, and on one of the test plats a complete commercial fertilizer gave better results than incomplete applications, although sulphate of potash alone gave a satisfactory return. Sulphate of ammonia gave a larger increase in yield than nitrate of soda. For sandy loams the use of 1 cwt. of sulphate of ammonia, 3 cwt. of superphosphate, and 1½ cwt. of sulphate of potash, given with a medium dressing of barnyard manure, is recommended.

**Trial of varieties of potatoes, G. E. ADAMS** (*Rhode Island Sta. Bul. 111, pp. 61-74*).—The fertilizer formulas used during a period of 7 years in potato experiments are given and the average yields of varieties for the number of years grown are shown in tables.

The range in yield of the 85 varieties under test was from 426 bu. per acre, the 3-year average of the Great Eastern, to 67.7 bu. per acre, the 2-year average of Rival. The total crop of Astonisher, Gem of Arrostook, and Prof. Dr. Maercker showed a maximum variation of only 0.9 of a bushel, yet in the percentage of merchantable tubers there was a variation of 26.4 per cent of the entire crop. A similar relation was observed between Commercial, Early Maine, and German Early Rose, the difference in yield of merchantable tubers in these 3 varieties being equal to 49.9 bu. per acre. In observing the disease resistance of varieties Prof. Julius Kühn showed the greatest immunity from injury by the blights. The selection of early-maturing varieties is considered as apparently the only safe plan to be followed to keep the crop free from blight.

Potatoes were sprayed 4 and 5 times during the season. Sixteen varieties gave an increased yield of over 50 per cent of the total crop as due to the additional spraying. Fifteen varieties showed an increase of from 25 to 50 per cent, 12 yielded from 1 to 25 per cent greater crops, while 8 varieties showed an apparent loss from the last spraying. The plants of the 15 varieties giving the greatest increase in yield remained vigorous and continued to grow from 2 to 3 weeks longer upon the area sprayed 5 times than upon the area sprayed only 4 times. Peerless Junior, State of Maine, Burbank, White Star, and Vermont Golden Coin, sprayed 5 times, retained from 90 to 100 per cent of their foliage for more than 3 weeks after the plants sprayed only 4 times were dead.

**Home-mixed fertilizers for potatoes, C. D. WOODS and J. M. BARTLETT** (*Maine Sta. Bul. 126, pp. 41-44*).—The details of experiments here reported have been previously noted (E. S. R., 16, p. 1073). In 1905 three home-mixed fertilizers were compared with one commercial potato fertilizer and the results, on the whole, were lower with the home-mixed than with the commercial fertilizer. The results are considered as not admitting of conclusive interpretation at the present time.

**Ramie and similar crops in India, G. B. DE CARDO** (*La ramie et ses analogues aux Indes Anglaises. Paris: A. Challamel, 1906, pp. 123*).—This book is a translation and a résumé of information on the culture and preparation of ramie and other analogous fiber plants in India. The information here given is taken from the Dictionary of the Economic Products of India, by G. Watt, published from 1889 to 1893.

**Field observations upon the tolerance of the sugar beet for alkali, G. W. SHAW** (*California Sta. Bul. 169, pp. 29, figs. 20*).—Previous work along this line,

described in earlier publications of the station (E. S. R., 8, p. 683; 12, p. 942), is briefly summarized. The later observations here recorded were made by the author at Grand Junction, Colo., in 1900 and at Oxnard, Cal., in 1904.

The investigations in Colorado indicated that in the virgin soils under test the heavy percentage of alkali lies above the fourth foot, and that the excessive amounts found in the upper foot have been brought there from that depth by shallow irrigation and by the upward leaching of the soil due to seepage. The average of 8 soluble salt determinations upon soils producing either good or fair crops of beets shows a percentage of 0.036 of chlorids, 0.004 of carbonates, and 0.087 of sulphates, or a total of 0.127 per cent in the upper foot of these fields. These figures correspond to 1,440 lbs. of chlorids, 160 lbs. of carbonates, and 3,480 lbs. of sulphates, or a total of 5,080 lbs. of soluble salts in the upper acre-foot. The yields of beets ranged from 7.76 tons to 20.98 tons, or an average of 8.45 tons per acre, with an average sugar content of 16.03 per cent and a purity of 81.8.

Soils producing poor crops of beets under the same conditions of cultivation and treatment were found to carry much more chlorid in the top foot than was held in the upper 3 ft. of the soils producing fair crops. These data are regarded as showing that the soluble salt content of the soil is the primary cause of the failure of beets, but it is pointed out that the high percentage of alkali is not uniform throughout the locality, and that by proper selection of soils these difficulties may be avoided.

The strength of the soil solution was determined as based on 20 and 10 per cent of moisture in the soil. It was found that the heavy adobe soil 2 days after irrigation contained from 18 to 20 per cent of water, while several days after irrigation the moisture content had fallen from 8 to 12 per cent and the plants were suffering from lack of water. As shown by the analyses made, the solution in soil with 20 per cent of moisture contained 2.97 per cent of alkali, and with 10 per cent of water in the soil 5.86 per cent. It is pointed out that when the density of a soil solution becomes too great the vitality of the seed is destroyed or, in the case of already growing plants, the passage of water from the soil into the plant is checked.

At Oxnard, Cal., observations were made in fields with a marked unevenness of stand, which frequently characterizes beet fields on alkali soils. The results on all the different fields pointed to the fact that wherever the chlorid content of the soil approached 0.20 per cent beet culture was unsuccessful. It was further shown that the sulphates had a comparatively limited effect on the growth of beets. The effect of the different salts is more clearly brought out in the following table:

*The effect of different percentages of soluble salts on the growth of sugar beets.*

Condition of beets.	Sulphates.	Carbonates	Chlorids.	Total salts.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
No growth .....	0.4068	0.0092	0.1957	0.6112
Poor .....	.8662	.0000	.0742	.4344
Fair .....	.2010	.0014	.0716	.2800
Good .....	.2629	.0101	.0419	.3149

On this particular field the sugar content of the beets ranged approximately from 17 to 22 per cent.

In certain portions of these fields where good beets were produced, practically all the alkali was found in the top foot of soil, where it could have little or no effect on the more delicate feeding roots of the plant, while on adjacent spots producing no beets the concentration of the alkali was essentially the same in the first and the second foot of soil, bringing it within reach of the fibrous-feeding roots. These results are regarded as indicating that the distribution of the soluble salts within the soil may be a more important factor than the total quantity of alkali present, and

also as explaining why beets fail to grow in certain places although little or no alkali appears near the surface. The failure of plants, even though the seed germinated well and a good stand was originally obtained, is also accounted for by this fact. In these observations fair beets were found growing in soil with an average of 4,000 lbs. of chlorids per acre-foot, and it was noticed that certain individuals have a much greater resistance to alkali than others. It is believed that the success of beet culture in regions with alkali soils depends upon the proper soil selection and the development of a more alkali-resistant beet.

**Sugar beets in the San Joaquin Valley**, G. W. SHAW (*California Sta. Bul.* 176, pp. 27, figs. 11).—The results of field observations and analyses connected therewith since 1902 are reported.

In 1902 the average results of 9 tests showed a sugar content in the beet of 14.9 per cent and a purity of 83.5, but the average yield was only 4.74 tons per acre. These figures are regarded as showing that the general climate and soil conditions are suitable for the production of high-class sugar beets. The low tonnage was largely due to late planting. A satisfactory yield can be obtained only by early planting, which will allow the plants to make considerable growth before the hot weather of the summer months.

These conclusions were confirmed by results obtained in 1905. It is also stated that, in general, the results will be very unsatisfactory when the beets are grown without irrigation. The failure of the plantings of 1905 was primarily due to late planting and inadequate irrigation, and in a lesser extent to poor soil preparation, poor cultivation, and beet blight. General discussions on the climatic conditions, moisture and sunshine requirements, and on soils and their preparation and cultivation are given, and the results of earlier experiments conducted by the station with sugar beets in southern California are reviewed in an appendix.

**Manurial experiments with sugar cane in the Leeward Islands, 1904-5**, D. MORRIS (*Imp. Dept. Agr. West Indies, Pamphlet 39, 1906, pp. 51*).—A summary of the results with seedling and other canes at the experiment stations in the Leeward Islands is given.

At Antigua the results showed that the canes B. 156, Sealy Seedling, B. 306, B. 208, D. 74, D. 95, and D. 109 are specially worthy of attention. The ratoons of 6 of these canes also ranked first at the various stations. In St. Kitt's Caledonian Queen and White Transparent gave the best results, while the Barbados seedling canes B. 208 and B. 147 were also satisfactory. The ratoon crop of B. 208 ranked first with a yield of 30 tons of cane and 8,508 lbs. of sugar per acre in the juice.

**Relating to the sugar industry in Peru**, T. F. SEDGWICK (*Trujillo, Peru: Haya, Verjel & Co., 1905, pp. 78, pls. 11, charts 3*).—This book contains descriptions of the sugar districts and sugar estates in Peru and a review of the methods of sugar-cane culture in that country, together with a brief discussion on the manufacture of cane sugar and the utilization of by-products. Comparative data from different sugar-growing countries are also given. Special reference is made in this work to the sugar estate known as Hacienda Cartavio.

**Germination of seeds as affected by nutrient salt solutions**, O. KAMBERSKY (*Zschr. Landw. Versuchs. Oesterr., 9 (1906), No. 1, pp. 32-43*).—Work along this line by several investigators is reviewed, and results of experiments at the seed control station at Troppau are reported.

Of each of 15 different field crops 400 seeds were soaked for 48 hours in a solution of a mixture of ammonium and potassium nitrate and sodium and ammonium phosphate. For the purpose of a check test the same number of seeds of each crop were soaked in water for the same length of time. When these samples were subjected to a germination test the seeds soaked in the nutrient salt solution did not sprout so quickly and, with the exception of sugar-beet seed, did not show as high a percentage of germination as the seed soaked in water.

The various crops showed different degrees of resistance, which is believed to be partly due to the age of the seed, although it was observable in fresh seed with a weakened vitality. All degrees of vitality were represented in each individual sample, and it is concluded that the weakest seeds lost their power to germinate when soaked in the salt solution, while in the resistant seeds the germination was delayed. It was also found that the parts of the embryo were differently affected, the plumule appearing more resistant than the radicle. Seeds of grains taken from the germinating chamber and transferred to fresh soil continued their growth normally, but were retarded as compared with seeds not treated with the salt solution.

**Seed inspection,** C. D. WOODS and BESSIE G. TOWER (*Maine Sta. Bul. 125, pp. 26*).—This bulletin contains the text of the Maine laws regulating the sale of seeds, and the results of analyses of samples of seeds collected by the station in 1905 and received from correspondents from 1902 to 1905. A list of weed seeds from the samples tested is given and attention is called to the free analysis of weeds, seeds, fertilizers, and feeds by the station.

## HORTICULTURE.

**Department of agriculture and horticulture,** V. A. CLARK (*Arizona Sta. Rpt. 1905, pp. 10-15*).—Attention is called to the intense heat and light in Arizona and the effect of these on plant growth. Shading has been found a specific for many crops which are injured or even killed in the open. Where the summer heat raises the surface soil to so high a temperature as to interfere with root growth mulching has been found a specific remedy. Deep planting of trees has also been practiced successfully to overcome this trouble.

The results secured at the station with a number of fruits and vegetables during the season are briefly stated. Guavas have been successfully grown, both in the open and in shade, and withstand a temperature of 19° F. The McNeal variety of garden pea was less injured by frost than the American Wonder variety. A study is being made of varieties of olives in Arizona. No insect nor fungus pest has been found as yet to attack this crop.

Some alfalfas from Sahara and Arabia promise to surpass the strain commonly raised at the station in growth during the hot months. The yields of 3 varieties of durum wheats in comparison with the Sonora variety are given. In every case the yield was considerably higher, and the straw, though taller, showed less tendency to lodge. It also rusted much less. Pea plants from light-weight seed died as a result of weather conditions a number of days earlier than from heavy seed. It is believed that considerable valuable work can be done along the line of seed selection.

**Report of the horticultural department,** J. TROOP (*Indiana Sta. Rpt. 1905, pp. 19-21*).—An outline of the experimental work of the department during the year, with some of the chief results obtained. In the use of pedigreed strawberry plants the results of a single season's work indicate clearly that "the pedigree theory as applied to strawberry plants has been overdone."

In some fertilizer experiments with tomatoes great differences in the productiveness of individual vines, due to individuality, were observed. In spraying experiments it is found just as essential to spray for the second brood of codling moth as for the first brood. San José scale has been found in 44 counties of the State. A new aphid was discovered during the summer of 1904, which seems to be especially partial to Houghton gooseberry bushes. The aphid is briefly described and has been given the name of *Aphis houghtonensis*.

**Fruits and vegetables,** E. B. FERRIS (*Mississippi Sta. Bul. 87, pp. 2-7*).—An account is given of the commercial culture and marketing of a number of varieties of fruits and vegetables, including potatoes.

The best results with strawberries have been secured with the Klondyke variety. The most effective fertilizer was a mixture made up of 200 lbs. of cotton-seed meal, 400 lbs. of acid phosphate, and 100 lbs. of kainit. The yield with this fertilizer was at the rate of 191.6 crates per acre. These results with berries, as with all the other crops experimented with, showed that the soil is lacking in phosphoric acid. On account of the scarcity of labor and poor shipping conditions the northern limit of successful marketing was Birmingham and Chattanooga. The best shipping package was a 24-qt. ventilated crate. The returns from 275 24-qt. cases netted a little less than \$500.

Asparagus was marketed most profitably in Chicago. Twenty  $\frac{1}{2}$ -bu. boxes gave a net return of \$30. When commercial fertilizers were used on cabbage, the increase over unfertilized plats was 223 per cent, and 299 per cent on soil that had been parked with cattle. The normal fertilizer used on this crop was 430 lbs. of cotton-seed meal, 420 lbs. of acid phosphate, and 200 lbs. of kainit. When either the cotton-seed meal or acid phosphate was decreased the crop was lessened, but when the kainit was decreased the yield remained practically the same.

Wardwell Kidney Wax beans averaged 120.8 bu. per acre, and Improved Valentine 121.6 bu., counting 30 lbs. to the bushel. The use of kainit was without effect in increasing the yield of this crop, but both nitrogenous fertilizers and phosphates gave marked increased yields. The unfertilized soil yielded 66 bu. per acre. When fertilized with a mixture containing 209 lbs. of cotton-seed meal, 114 lbs. of dried blood, 455 lbs. of acid phosphate, and 213 lbs. of kainit the yield was 150 bu. per acre. One-half of this fertilizer mixture gave a yield of 121.5 bu. per acre. When the nitrogen was left out of the mixture the yield was 82 bu. per acre. Acid phosphate alone produced a yield of 104.5 bu. per acre. The net returns from shipping 2 acres of beans to northern markets was \$173.29. The bushel hamper was a much more desirable package for this crop than the bushel box.

Burbank was the heaviest yielding variety of potato grown, producing 182.5 bu. per acre. Native seed produced but 70.6 bu. per acre, while with at least 5 varieties from other sources the yield was in no instance less than 126.8 bu. per acre. The net returns from 2 acres of potatoes were \$112.

A test was made with different sized seed pieces, varying from 1 eye to whole medium sized tubers. The yield with one-eye pieces was 68.9 bu. per acre, and this was gradually increased to 107.9 bu. when whole potatoes the size of a guinea egg were used. Among other vegetables grown were onions, beets, radishes, kohlrabi, turnips, ruta-bagas, eggplants, and peppers. The only ones profitably marketed were beets, ruta-bagas, and turnips.

**Further studies in lettuce culture,** W. STUART (*Vermont Sta. Rpt. 1906, pp. 292-296, pl. 1*).—In an earlier report (E. S. R., 17, p. 249), an account was given of an experiment to determine the comparative value of different forms of chemical fertilizers, the relative value of chemical fertilizers and rotted manure, and the relative influence of surface *v.* subwatering for lettuce. In the present instance a report is made on flat-grown *v.* bench-grown plants; and combination indoor and outdoor lettuce culture.

In the first experiment plants were grown in flats until ready for market. The flats were 12 by 16 by 3.5 in. One dozen plants were grown in each. Similar plants were grown in benches at a distance of 8 by 8 in. apart. The bottom of the flats was filled to a depth of 1.5 in. with well-rotted manure. Thirty-four square feet of space were given to each method of culture.

The plants in the flats were ready for market a week in advance of those in the bench. Their average weight was 86 gm., while those in the bench averaged 210 gm. each. The flat-grown plants presented a good appearance and sold for 40 cts. per dozen, while the bench-grown plants commanded but 50 cts. per dozen. From the

standpoint of space, therefore, the returns per square foot were 26 cts. from flat-grown plants and but 10 cts. from bench-grown plants.

The conclusion is drawn that for local market conditions a greater net profit can be made from lettuce planted in flats. The growing of the plants in flats to maturity considerably lessens the labor required, though the lettuce is not so heavy nor so good by close planting as when sufficient space is allowed for development.

In the combination indoor and outdoor lettuce culture, lettuce was started in the greenhouse and transplanted to the open as soon as weather conditions permitted. Good crops were thus secured. The average weight of the plants of a number of different varieties grown for 2 years is tabulated. Iceberg gave the heaviest yield in each of the 2 years. It is believed that seedlings could be grown equally as well in the hotbed as in the greenhouse for this work, and that in the vicinity of the station this method of culture would be very profitable.

**Fertilizer experiments in field culture of garden peas** (*Maine Sta. Bul.* 126, pp. 30-34).—Garden peas were grown for a cannery on 2 farms. Part of the peas grown was inoculated with pure cultures of nitrogen-fixing bacteria from the Department of Agriculture and from commercial sources. Commercial fertilizer was used on both farms. A severe drought seriously interfered with the experiment.

On one farm the soil was found to be thoroughly inoculated with the nitrogen-collecting bacteria, and the use of pure cultures was without additional benefit. On the other farm which, so far as known had never been planted to peas, some of the plants on the inoculated plats were found to contain tubercles on the roots, but no more than on some of the other plants which were not inoculated.

**The cassaba melon** (*Pacific Rural Press*, 71 (1906), No. 10, p. 148).—The history of this muskmelon, also known as Winter Pineapple Muskmelon, is given, with an account of its introduction into the United States, and the methods observed by the author in its culture. This is a late melon, suitable for Christmas use, and grown to some extent as a stock food.

**Report of culture experiments in 1905 on the sewage fields of Berlin**, J. KLAR and O. MENDE (*Gartenflora*, 55 (1906), Nos. 2, pp. 35-40; 3, pp. 66-70).—The results are given of tests in growing large numbers of flowers and vegetables, with brief comments on the various varieties.

**Soil sterilization**, W. STUART (*Vermont Sta. Rpt.* 1905, pp. 297-299).—A historical account is given of the development of soil sterilization by means of steam and otherwise in this country, with an account of the author's investigations in sterilizing soil in solid beds and subwatered benches.

"Three in. drain tiles were sunk about 10 in. below the surface of the soil. The lines of tile were laid every 16 in., each line being independent of the other and connected with the surface by a vertical section of drain tile." When steam was properly connected and turned in the tile at a pressure of 40 to 60 lbs., a bed containing approximately 70 sq. ft. of surface could be heated up to about 210° F. in about 3 hours' time. When the surface soil was well covered with burlap, the heat was maintained at this temperature for a long time, and was entirely effective against nematodes. This method of soil sterilization involves less labor than the usual method of sterilizing in boxes, as there is no handling of soil and the drain tiles are far enough below the surface to be out of the way of cultural operations.

A large portion of the bench surface in the greenhouse is fitted for subwatering by means of galvanized iron pans and layers of porous brick. An attempt was made to sterilize the soil in this bench by injecting steam into the pan through the watering tube. The result was unsatisfactory, as too much steam was required. Much of the steam condensed in coming in contact with the cold porous bricks, and it is believed that it would be more economical to employ a sterilization box in the treatment of soil in subwatered benches.

**How to use a planting plan,** I. G. TABOR (*Gard. Mag. [N. Y.], 3 (1906), No. 3, pp. 146, 147, chart 1*).—A complete chart is given for planting a 50 by 100 ft. lot. The plan shows the kind of trees, shrubs, and flowers to plant, just where each one should be planted, and the method of transferring a planting plan to the ground.

**Blossoming of fruit trees,** L. B. JUDSON (*Idaho Sta. Rpt. 1905, pp. 23-32, charts 3*).—The blossoming season of a large number of varieties of apples in different parts of Idaho in 1904-5 are tabulated, as well as the blossoming season for 12 varieties of pears and 5 varieties of peaches for the season of 1905.

**On the winter injury of apple trees,** W. STUART (*Vermont Sta. Rpt. 1905, pp. 299, 300, pls. 2*).—A further note is given on the injury to apple trees during the winter of 1903-4, mentioned in an earlier report of the station (*E. S. R., 17, p. 249*). The winter-injured trees after blossoming and partially leafing out apparently stopped growth and the unfolded leaves shriveled and died. Later in the season many of the trees pushed out into new growth, usually at the base of the scaffold limbs, or somewhat higher up.

Experiments were undertaken to see if the trees would not be benefited by pruning. A number of eight-year-old Rhode Island Greenings were severely pruned back, others less vigorously handled, and some not pruned at all. It was thought that the severe pruning of the trees on which new growths were being pushed out at the base of the limbs would tend to throw the strength of the tree into a few branches, and thereby induce greater growth and a more shapely head. The orchard was not given good cultivation.

The growth made on the differently handled trees is shown in a series of illustrations. "A careful study of this series of photographs affords little evidence that pruning was beneficial." As a result of the investigations, the author recommends that pruning operations be deferred to the latter part of the growing season or the following spring, rather than immediately after such winter injury as noted in the experiment. Severe pruning is inadvisable.

**Influence of stock on scion,** W. STUART (*Vermont Sta. Rpt. 1905, pp. 300-305*).—In 1899, 5 classes of plums were root grafted on 4 types of stocks. The stocks used were Americana, Wayland, Marianna, and Peach, and the scions were Stoddard of the Americana group, Green Gage of the Domestica group, Chabot of the Japanese group, Milton of the Wild Goose group, and Newman of the Chicasaw group.

The results secured with this combination of stocks and varieties in Maryland have been previously noted (*E. S. R., 14, p. 1069*). The present report covers the results secured in Vermont from 1900 to 1905. Tabulated results given in the report show that 93 per cent of the varieties on Americana roots lived, 100 per cent on Wayland, 80 per cent on Marianna, and 40 per cent on Peach. The average diameter of the trunk of the trees produced on these different stocks is shown in the table below, the measurements being made at the collar and 1 ft. above the collar:

*Trunk growth of varieties of plums on different stocks.*

Variety of plum.	Americana.		Wayland.		Marianna.		Peach.	
	Collar.	Foot above.	Collar.	Foot above.	Collar.	Foot above.	Collar.	Foot above.
	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.
Stoddard.....	2.00	1.75	1.69	1.82	1.69	1.44	.....	.....
Green Gage.....	2.88	2.19	2.72	2.56	2.69	2.50	2.50	2.31
Chabot.....	2.50	2.31	3.19	2.00	2.72	2.53	.....	.....
Milton.....	2.41	2.00	2.50	2.22	3.28	3.19	1.03	.88
Newman.....	3.03	2.69	3.16	2.97	3.03	2.97	2.88	2.75
Average.....	2.46	2.19	2.65	2.41	2.68	2.53	2.14	1.98

"These measurements show that Stoddard on Americana gives the greatest average diameter of the trunk, with Marianna and Wayland about equal. Green Gage did best on Wayland, with Marianna a close second, Peach and Americana being third and fourth, respectively. Chabot was best on Wayland and second best on Marianna. Milton was far superior on Marianna than on any other, Wayland and Americana occupying second and third places. Newman did well on all stocks, but was slightly superior, in diameter at least, on Wayland, followed by Marianna, Americana, and Peach in the order named. . . . Stated briefly, Americana seems best for Americana; Wayland for the Japanese; Milton for Marianna, with little choice between Wayland and Marianna for the Domestica group, and no marked choice between any of the four stocks for the Chicasaw group."

The influence of Wayland stock on Milton variety is given special mention. On Wayland the Milton grew more or less upright, while on Marianna the head was low, bushy, and spreading. The variety Newman made especially good growth on Peach roots, and it was suspected that roots might have been sent out by the scions. Some of the trees were dug up, but in only one instance was this found to be true, and this exception is not considered of any vital importance.

"A comparison of the root systems showed the Peach to be the deepest rooted and least spreading. Marianna and Wayland possessed numerous spreading and rather shallow lateral roots. Americana, while having a spreading lateral-root system, was not as symmetrically developed as were the two former. In none of them could the root system be said to be much superior to that of Peach stock." Milton on Marianna stock was much more seriously affected by "plum pocket" than when grown on Wayland or Americana. Whether it was due to stock or not could not be told.

**Hybrids in their relation to grafting and wines** (*Bul. Agr. Algérie et Tunisie*, 11 (1905), Nos. 23, pp. 524-530; 24, pp. 550-557).—The essential part of this article is an address delivered by L. Daniel before the Viticultural Society of Lyons, in which he reviews his work on grafting in the improvement of grapes, and points out its practical application.

It appears that the best French varieties of grapes can not be improved from the standpoint of the fruit by grafting, but may be improved from the standpoint of resistance. The case is different with hybrids, where opportunity for amelioration by grafting is much greater, since not only can the resistance to phylloxera be thus increased, but the crop greatly modified.

Variations produced by grafting seem often to be hereditary in the vine. It may thus happen that many old varieties may be materially modified in time. In order to avoid this, it is recommended that experimental vineyards be established in which the old French varieties of grapes, which have been originated with such great care, may be preserved in their purity.

**Variation by grafting**, G. BONNIER (*Fermes et Châteaux*, 1 (1905), No. 4, pp. 6-8, figs. 5).—A popular and somewhat extensive review of the work of L. Daniel on grafting between different species of plants, and on the hybrid variations obtained. The review covers the results of the grafting experiments noted more at length in earlier numbers of the *Record*.

**Study of the cider apples of Sarthe**, P. L. C. CASSARINI and E. POUPARD (*Bul. Mens. Off. Renseign. Agr. [Paris]*, 5 (1906), No. 2, pp. 157-179).—A general account is given of the cider regions of Sarthe, and of the varieties of apples used in cider production. The various varieties are described in considerable detail, and a table given showing the vigor and hardiness of different varieties when grown on the various soils of different regions, the yields obtained, quality of fruit and cider made from it, with analyses of the ciders.

**Olives and citrus fruits** (*Louisiana Stas. Rpt.* 1905, pp. 9, 10).—During the year 1 variety of olive, *Pensulina*, produced fruit which was successfully pickled. The fruit is of fine flavor and medium size. It is believed that these are the first olives to be grown to maturity and pickled in Louisiana. Citrus hybrids produced by

this Department by crossing *Citrus trifoliata* with sweet oranges have withstood a temperature of 18° F., the coldest weather at the station since they were planted.

**Varieties of dates of Tagant and Adrar.** R. ARNAUD (*Bul. Agr. Algérie et Tunisie*, 12 (1906), No. 3, pp. 60, 61).—A list is given of the species of dates grown in these regions, the names being given in both French and Arabic, and comments added as to the usefulness of some of the varieties.

**Tropical fruits on the Florida Keys.** P. J. WEBSTER (*Fla. Agr.*, 33 (1906), No. 9, pp. 161, 162).—An account of the methods of culture of the tropical fruits grown on the Florida Keys, including pineapples, avocado, mangoes, sapodillo, bananas, sugar apples, soursop, custard apples, eggfruit, papaw, pomegranate, etc.

**Miscellaneous fruit notes.** W. STUART (*Vermont Sta. Rpt.* 1905, pp. 305-309).—Tables are given showing the blossoming, leafing out, and ripening periods of plums and cherries for the years 1903 to 1905, inclusive. The data show a close relationship between the time of flowering and the time of fruiting. Recommendations as to the best varieties of plums and cherries are given.

**Growing fall bearing strawberries.** S. COOPER (*Amer. Agr.*, 77 (1906), No. 13, p. 429, fig. 1).—The Pan-American and Autumn varieties of strawberries that bear fruit in the fall are described and methods given for their cultivation. In the case of the Pan-American variety it is stated that by judicious cultivation and systematic removal of the early blossom stems this variety will continue to bear until the green berries are frozen. An illustration is given of the plant in blossom and fruit.

**The transportation of fruit in refrigeration.** G. H. POWELL (*Cal. Fruit Grower*, 33 (1906), Nos. 919, pp. 1, 3; 920, p. 5).—A paper presented before the American Society of Refrigerating Engineers at its meeting in New York, December 4, 1905, in which the losses that occur in shipping perishable fruits in refrigerator cars are discussed.

Where fruits are shipped from the orchard without first cooling and are from 3 to 10 days in transit, large losses occur, particularly in the top tiers of fruit. The problem to be overcome is to secure refrigeration which will be sufficient to cool down all parts of the car sufficiently to prevent the development of decay, either by improved methods of car refrigeration or by cooling down the fruit before it is placed in the refrigerator car. Coupled with these requirements is the necessity of having the car refrigeration simple so that an ordinary brakeman could manipulate it satisfactorily.

**The cocoanut and its relation to the production of cocoanut oil.** H. S. WALKER (*Philippine Jour. Sci.*, 1 (1906), No. 1, pp. 53-81, pls. 10).—This is a report of an extensive study of cocoanut production from the standpoint of quality and quantity of the oil yielded.

Analyses are given of the seashore and interior soils on which cocoanuts grew successfully, and of nuts picked at varying stages of ripeness, nuts from different localities, and nuts grown on both sandy soils and clay soils. It had been noticed that cocoanut trees growing near the seashore at San Ramon produced much more fruit than trees standing farther inland. Analyses showed the inland soils to be somewhat superior in the elements of fertility to the seashore soils, but were much less permeable.

The following table shows the fertilizing constituents contained in the husk, shell, meat, and milk of cocoanuts:

*Analyses of cocoanuts.*

Part.	Nitrogen.	Potash.	Phosphoric acid.
	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
Husk .....	1.609	3.915	0.017
Shell .....	.660	.947	.459
Meat .....	4.683	2.475	1.740
Milk .....	1.542	1.313	.171
Total .....	8.494	8.650	2.387

It is calculated that 1 hectare of land on which 173 trees are growing will produce a total of 7,000 nuts per annum, and that each tree will lose annually 16 leaves, weighing about 3 kg. each. From these data it is calculated that the total annual drain on the soil per hectare from growing coconuts is as follows: Nitrogen, 91.12 kg.; potash, 135.37 kg.; and phosphoric acid, 41.38 kg. Based on these data and the analyses of seashore soil it is calculated that the seemingly barren seashore soils on which coconut trees are growing so vigorously contain sufficient nitrogen to produce crops for 307 years, sufficient potash for 1,478 years, and phosphoric acid for 677 years, not taking into account the probable inexhaustible supply of plant food constantly coming down in the seepage water from the interior hills. While irrigation and fertilizing may be of considerable value to trees in the interior, on the seashore irrigation would be of value only in dry seasons, and fertilizers would probably be washed away before they could be used by the trees.

The analyses of the nuts at different stages of growth are given in an extensive series of tables. They show that there is no indication of meat or fatty material in the nut until it has reached its maximum size and the shell is completed. With the formation of the shell the milk becomes rather sweet, and a slimy, pulpy mass, having a sweetish taste and comparatively little oil, begins to deposit on the inside, chiefly on the lower half of the nut. Gradually it extends over the whole of the inside of the nut, becoming denser and thicker and increasing in oil content at the expense of the sugar in the milk. This hardening process continues often in ripe nuts for 2 or 3 months after they have been picked from the tree, or until the nut sprouts.

With the appearance of the sprout the fat stored up in the nut is transformed into sugar and other bodies, and the embryo gradually increases in size until it occupies the whole space inside the nut and utilizes all the nourishment contained therein for its growth. In order, therefore, to secure the largest yield of copra and oil, only thoroughly ripe nuts should be used, and the author states that it is often advisable to allow these to stand in a dry place for a few weeks before they are opened. By the use of green nuts it is shown that there may be a loss of almost 50 per cent, while if nuts are stored for more than 3 months there is a loss due to germination, and often before that time nuts which have been cracked or bruised in gathering become rancid.

Analyses of different colored nuts—golden yellow and light green, both of which turn brown at maturity—show practically no difference in composition. The quality of nuts grown on the seashore, contrary to general statements, was not found to be superior to those taken from trees farther inland. Among 1,000 nuts from the seashore, gathered at random, 55 were found in bad condition, while out of the same number, gathered from the interior, only 15 were spoiled. This difference, it was thought, was due to the harder grounds along the seashore and the consequent greater bruising in falling.

Analyses are given of nuts from Davao. One variety was from trees producing large nuts, rather pointed in shape, and the other from trees bearing small, rounder fruit. The percentage of oil in the nuts free from husks was found to be about the same in both cases.

**The seed grower**, C. JOHNSON (*Marietta, Pa., 1906, pp. 191, pl. 1*).—This book, believed by the author to be the first of its kind published in any country, gives detailed directions for the production of all the different kinds of vegetable and flower seeds commonly grown in the United States. A section is also devoted to bulbs and shrubs. The usual field-crop seeds, such as clover, wheat, etc., are not considered. Suggestions for originating new varieties, forms of contracts made by seed growers with seed dealers, cultural hints for the ordinary garden crops, germination, color, and vitality of seeds, and descriptions of a number of the more prominent varieties of each of the different vegetables are included.

The author states that to a large extent America still depends upon European growers for the best quality of beet, cabbage, carrot, cauliflower, kale, kohlrabi, leek, parsnip, parsley, radish, turnip, spinach, and onion seeds, and the choicer grades of flower seeds and bulbs. America satisfactorily produces pea, bean, celery, cucumber, lettuce, melon, and certain kinds of onion seeds, as well as all the more usual field-crop seeds. Much the larger amount of flower seed produced in the United States is grown in California.

## FORESTRY.

**History of the lumber industry in America**, J. E. DEFEBAGH (*Chicago: Amer. Lumbermen, 1906, vol. 1, pp. XIII+559*).—A large amount of material is here brought together relative to the history of the lumber industry since the discovery of America. Twenty-three of the 31 chapters deal with the industry in Canada. In one chapter the forest geography of North America is considered. In the 6 chapters devoted to the industry in the United States one is concerned with the forest resources, one with the public land policy in its relations to lumbering, one to forestry and forest reserves, one to tariff legislation, one to lumber production, and one to foreign trade.

**Forestry statics, a handbook for the advanced silviculturist**, H. MARTIN (*Die Forstliche Statik. Ein Handbuch für leitende und ausführende Forstwirte sowie zum Studium und Unterricht. Berlin: Julius Springer, 1905, pp. XII+361*).—Part 1 of this work deals with the principles and methods of forestry statics, and part 2 with their application. The various chapters of part 1 take up the production of wood volume through accretion, the value and uses of wood, the production and cost of forests, and the net profits. The work is intended for the use of students and teachers.

**Handbook of the timber trade**, L. HUFNAGL (*Handbuch der kaufmannischen Holzverwertung und des Holzhandels. Berlin: Paul Parey, 1905, pp. VIII+318, figs 28*).—This book treats of the different commercial grades of lumber and timbers, the commercial uses of different kinds of timbers, transportation of timber, etc.

**Forestry problems in the United States**, T. P. IVY (*Boston: The Archway Book-store, 1906, pp. 47*).—The author criticises present methods of conducting civil-service examinations for positions in the forestry service, discusses the effect of the Reserve Act of 1891, which he believes has had the result of considerably increasing the price of lumber and forest products, and urges more extensive silvicultural operations in the East. As a means of broadening our forest administration he suggests a board of forest conservators of at least 7 members. A discussion is also given of the Mississippi River in its relation to forestry.

**Future forest trees**, A. H. UNWIN (*London: T. Fisher Unwin, 1905, pp. 108, pls. 3*).—There are 3 chapters in this book, the first dealing with the German timber imports from the United States and Canada; the second with the general results of planting experiments with American trees in Germany, Austria, Great Britain, and Switzerland, and the third with the silvicultural characteristics and treatment of the various American species of trees. The purpose of the book is to present in a concise manner the results of European experiments with imported American trees, most of which are ornamental, for the benefit of English forestry.

**Forestry division**, K. A. CARLSON (*Orange River Colony Dept. Agr., Ann. Rpt., 1 (1904-5), pp. 45-123*).—This gives an outline of the forestry work of the division for the year, with an account of the forest reserves, individual plantations, nurseries, revenues, expenditures, etc.

About 2,700 acres are under the control of the forestry division, on 93 of which plantings have been made. The forestry division recommends that candidates be sent by the government to Yale College to take the 2 years' course of forestry. It is believed that forestry conditions in America are more nearly like those in South

Africa than elsewhere. The cost of the course is less than half that of the English course, and it can be completed in 2 instead of 3 years, as in Europe.

About 2,000,000 cu. ft. of timber was imported into the Colony in 1903, while the average yearly importation is about 700,000 cu. ft. It is estimated that the cost of establishing timber areas in the Colony, carried out on the scale of at least 2,000 acres per annum, would be about \$50 per acre, spreading over a period of 30 years.

**Report forest department of the Madras Presidency for 1904-5** (*Admin. Rpt. Forest Dept. Madras, 1905, pp. 167*).—This is a progress report covering the constitution of the state forests, their management and administration during the year, and financial results. The appendixes contain details regarding the acreage of forest areas in the different districts and circles, lands under settlement, forest tracts protected from fire, the outturn of timber, fuel, and bamboo, revenues derived from different sources, etc.

**Notes on the effects of frost on trees at the government nursery, Irene,** L. F. TAYLOR (*Transvaal Agr. Jour., 4 (1906), No. 14, pp. 325-329*).—Three methods were employed to protect trees known to be tender to frost during the winter. These were plant shelters, large screens, and covering with Hessian cloth. The plant shelters were the most effective, and were made of rough Eucalypt poles and thin branches. A framework was built of the poles about 6 ft. high, and over this thin branches were laid at intervals of about 1 to 2 in. Although the shelters do not keep out frost, they lessen its severity by preventing radiation, which is the cause of most damage to trees during the winter. The behavior of about 90 species toward frost is mentioned in detail.

**Planting white pine in Vermont,** L. R. JONES (*Vermont Sta. Bul. 120, pp. 67-80, figs. 7*).—An account is given of forestry conditions in Vermont, with directions for starting a pine forest, either with seeds, natural seedlings or nursery stock, and the after care to be given it.

On the University farms an experimental tree plantation was made some 8 years ago on a dry, sterile, sandy soil, originally covered with pitch pine. The trees planted were black locust, red oak, white birch, chestnut, cottonwood, box elder, European larch, Norway spruce, and white pine, but only locust and white pine have given promise of profitable return. There is some doubt as to whether locust will be able to survive the attacks of borers, but the white pine has proved an unqualified success. White pines that have been planted for 8 years now stand 7-9 ft. high and have made a growth of 2-4 ft. the last 2 summers.

The starting of a forest by sowing seed broadcast is believed to be a hazardous undertaking. Special attention is called to the fact that the year 1904 was a pine-seed year and that there is an abundance of 1-year-old seedlings now in the State, and that these may well be used for forestry purposes. On a small scale the trees may be obtained from nurseries. The estimated cost of producing trees in a nursery is placed at \$2 per 1,000. Maple trees can be bought for about half the price of white pine trees, and it is therefore more economical to plant about half and half maple and pine. Pines grow as well as in pure stands, and as soon as they overtop the maples they will kill out most of them. This will occur in about 20 years, and if this natural thinning is not sufficient the maples should be cut out.

**The catalpa tree for cross-ties** (*Arboriculture, 5 (1906), No. 3, pp. 69-81, figs. 8*).—This is a report of F. I. Brown, as chairman of the Committee on Roadway and Ballast of the Pennsylvania Railway, on the use of the catalpa tree for cross-ties, and is essentially a compilation of information on the value of *Catalpa speciosa* for lumber, posts, ties, etc.

**The value of cultivated rubber to the manufacturer** (*Trop. Agr. and Mag. Ceylon Agr. Soc., 25 (1905), No. 5, pp. 657-659*).—This paper was prepared by C. P. Fox, of Ohio, and is reprinted from the *India Rubber Journal*, August 28. It contains an account of experiments with a large number of varieties of rubber to deter-

mine their tensile strength. The data obtained are tabulated and the following conclusions drawn:

"Ceylon fine, when used to denote the oriental source of fine Para, means a grade lacking in uniformity when the tensile strength is considered. The curing qualities of Ceylon fine indicate that it has a decidedly slower action than the South American product. A future paper will show this difference more clearly. Mill deportment indicates that all of these oriental samples are much softer and are less nervous than the occidental types."

**The spiral system of rubber tapping**, I. ETHERINGTON (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 5, pp. 641-646, pl. 1).—A description of the spiral system of tapping worked out by C. Northway and E. D. Bowman on the Deviturai Estate in the Southern Province of Ceylon. This method of tapping is used on *Hevea brasiliensis*. It is employed only on trees which have a girth of 18 in. or more 3 ft. from the ground, or when about 5 years old.

The first time trees are only lightly tapped up to a height of 4 ft. from the ground, starting 1 ft. from the base of the tree. The first process is to mark the place for the spiral cut. This is done in stenciling ink with a sheet-tin guide. On young trees at the first tapping 2 spirals only are cut parallel and 1 ft. apart, each spiral going once around the tree. The spiral cuts are made at an angle of 45° or more; the younger the tree, the greater should be the slope. On older trees the spirals are continued up the tree to 6 ft. high or more.

The first cut in the trunk is made with a special knife, which is used as if it were a plane. The following day the cut is reopened with a paring knife having a steel spring, which works against the trunk to prevent cutting the cambium. On alternate days the shaving knife is replaced with a pricking tool, which is a small revolving spur fitted on a handle. This is run along the edge of the spiral cut, puncturing the bark close against the previous day's wound and along the wound surface. The object of the pricker is to save cutting away the bark so quickly. When the shaving knife alone was used it was found that 2 in. width of bark was cut away in one month, and when the pricker was used on alternate days only 1 in. of bark was removed per month. The flow of latex produced by the pricker seems just as full as that produced by cutting the bark.

The average yield of rubber by the V system of tapping on the estate was 1 lb. per tree per annum and by the spiral system 5 lbs. per tree per annum. In 1903, 248 trees of various girths gave 240 lbs. of rubber by the V tapping. These same trees the following season by spiral tapping yielded 1,317 lbs. of rubber. The tapped trees appear to be less injured under the spiral system than under the old V system of tapping.

In the case of young trees it is believed that tapping should not start until the trees begin to flower; that is, the fifth year. The labor required under this system is about 5 trained coolies per acre. Each cooly can tap about 400 lineal feet or 720 in. of girth per day, or 30 to 40 trees.

The yields from the trees noted above were obtained on swampy land not believed to be especially suited to rubber production. It is stated that this system of tapping is rapidly being extended.

**Ceara rubber in Brazil (*Manihot glaziovii*)**, A. MOULAY (*Un arbre à caoutchouc du Brésil, le Manisoba. Paris: A. Challamel, 1906, pp. 31, figs. 16*).—A botanical description is given of this species of rubber, with an account of its culture in Brazil, including methods of extracting the latex, and the production of hard rubber.

***Sapium aucuparium* in Ceylon** (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 3, pp. 425, 426).—It is stated that this tree is grown in Ceylon under the name of *S. biglandulosum*. It grows to a height of about 40 ft. and seeds freely. In tapping experiments the latex dried to a brittle resinous substance, and planters are advised to wait and see what products can be obtained by mixing the latex of this

species with that of Para rubber before planting extensively. Other species of *Sapium* found growing in Ceylon are *S. indicum*, *S. usigne*, and *S. sebiferum*. The seeds of the latter are coated with "tallow," which is used in the place of animal tallow for the manufacture of candles, soap, etc.

**Species of forest trees in Soudan.** M. CONSTANCIA (*Les essences forestières du Soudan, propres à la construction*. Paris: A. Challamel, 1906, pp. 68).—Descriptions are given of the various forest trees of French Soudan, with an account of their usefulness for various purposes.

**Philippine wood oils.** A. M. CLOVER (*Philippine Jour. Sci.*, 1 (1906), No. 2, pp. 191-202).—A chemical study was made of the oils obtained from a number of Philippine woods. The principal oils studied are the oil of Supa, obtained from the tree *Sindora wallichii*; Balao, or oil of Apitong, derived from various species of the genus *Dipterocarpus*, the chief use of which appears to be in calking small boats and as a protective varnish for woods; and Malapaho, or oil of Panao, from the tree *D. vermicifluus*.

### DISEASES OF PLANTS.

**Incomplete experiments for 1905.** L. F. HENDERSON (*Idaho Sta. Rpt. 1905*, pp. 14-22).—Brief accounts are given of a number of experiments which are in the main incomplete. The investigations included spraying for the prevention of apple scab and codling moth, combating pear blight and tomato blight, destruction of dandelions, spraying for the prevention of rose mildew and rose aphid, and spraying for the elm aphid.

The spray for the prevention of apple scab and codling moth consisted of Bordeaux mixture, to which was added some form of arsenical preparation, but the results were negative, no marketable apples being found in the orchard at the end of the season.

In the experiments with pear blight the wounds made by cutting out diseased portions of the trees were covered with a mixture consisting of sulphur and carbolic acid. This was used quite liberally in covering the wounds, and there seems to be some evidence to indicate that its use was followed by good results. The experiments with tomato blight were practically a failure, although plants from seed placed directly in the field where they were to stand were somewhat more promising than others.

In the eradication of dandelions the author applied kerosene, brine, and gasoline to the plants, and where gasoline was applied the dandelion was killed without any injury to the grass. The other treatments were not wholly efficient in destroying the weed and the grass was often destroyed for several inches about the point of application. A number of mixtures were tested for combating the rose mildew and aphid, the best results being obtained where whale-oil soap and potassium sulphid were combined.

Spraying for the prevention of elm aphid consisted of winter or early spring treatment with the lime-sulphur spray, and where well applied the trees were protected against injury. Thorough applications must be given the trees, so as to reach all the eggs, which are deposited in crevices of rough bark, especially toward the base of the trees.

**Indiana plant diseases in 1905.** F. D. KERN (*Indiana Sta. Bul. 111*, pp. 123-134).—A résumé is given of the plant diseases observed in Indiana in 1905, the data being compiled chiefly from reports by correspondents made in response to a circular letter sent out by the station.

The summary indicates the prevalence of the more important diseases and estimates the extent of injury as compared with the previous season, whenever possible. The various crops are taken up and under each are listed the diseases observed, and where any are known, methods are given for their prevention. Formulas are given for the preparation and use of fungicides in connection with combating plant diseases.

**The occurrence of plant diseases in Vermont in 1904,** L. R. JONES and W. J. MORSE (*Vermont Sta. Rpt. 1905*, pp. 267-271).—Data are given showing the mean temperature, rainfall, number of clear and cloudy days, etc., and the authors call attention to the close relationship between plant diseases and weather conditions.

Brief notes are given on a number of diseases observed during the period covered by the report, particular attention being given to those of the potato, and 2 new leaf spot diseases are described. The first of these diseases made its appearance early in July, a few plants showing small black spots on the leaves, which suggested the presence of early blight. Upon closer observation it was seen that the blackening began on the under side of the veinlets and spread more rapidly along the veins than laterally. No fungus was detected in connection with the spotting. One hill of affected potatoes was dug and the root system, tubers, and bases of the stem seemed sound. The other infected plants were kept under observation until the death of the plants in September. The spots gradually enlarged, still bearing a close resemblance to the early blight, but remained sterile.

In the authors' judgment it is a nonparasitic disease, involving the plant as a whole, the local spotting of the disease being merely a symptom. It is believed to be the same disease observed by one of the authors in Germany and also in England, and a similar trouble was noticed on specimens of the Mexican *Solanum polyadenium* in the horticulturist's potato collection.

The other disease appears to be unrecorded in this country and was first noticed on early planted Early Rose potatoes. The plants exhibited obscurely defined pale yellow spots  $\frac{1}{8}$  to  $\frac{1}{4}$  in. in diameter, and the lower surfaces of the spots were covered with a delicate gray growth, evidently a *Cercospora*. In the gross appearance of the spots and in its occurrence and destructiveness the disease was much like that caused by *Cladosporium fulvum*, which was developing at the same time on neighboring tomato plants. This disease spread during July to another variety of potatoes in an adjacent plat and showed slight development in other plats later in the season. It caused considerable damage from hastening the death of the vines of the earlier potatoes, but did no appreciable harm on the later varieties.

The fungus is being studied to determine its specific and cultural characters.

**The part taken by teleutospores and æcidia in the distribution of maize and cereal rusts,** J. C. ARTHUR (*Proc. Soc. Prom. Agr. Sci.*, 26 (1905), pp. 94-98).—Attention is called by the author to the recent discovery of the æcidial stage of corn rust on the common wood sorrel (*Oxalis* sp.).

Hitherto this form of the rust had not been known and knowledge of the life history of the fungus remained incomplete. Having discovered the æcidial stage of the rust, this gap is filled, but the author states that the usual infection is probably through the blowing of the uredospores from the regions where the corn is not completely killed by frost. The blowing northward of these spores may cause successive infections in new localities as the season advances, and thus spread the rust throughout the country. In addition the germinating teleutospores reach plants of *Oxalis*, from which direct infection to the corn plant becomes possible.

The distribution described above for the corn rust is said to apply almost equally well to some of the rusts of other cereals.

**Rust problems,** H. L. BOLLEY and F. J. PRITCHARD (*North Dakota Sta. Bul. 68*, pp. 607-676, figs. 30).—An account is given of rusts of cereals and other plants, the principal aim of the bulletin being to provide a compendium of the theories and known facts involved in the rusting of cereals and other important farm crops, to give the lines and results of new observations and experiments, and to cite investigations and farm practices which give promise of future success in combating or preventing crop destruction by these fungus pests. The authors describe various forms of rusts, giving an account of their effect on the host plants, the alternate generations of a number are mentioned, and accounts given of the method by which the fungus is carried over from one season to another.

Among the recent observations, attention is called to the fact that in connection with shriveled grains the authors found spore beds containing both uredospores and teleutospores beneath the bran layer, and this seemed to indicate that possibly the wheat rust could attack the plant directly from the seed. Infected seed generally may be recognized by black-pointed grains, the black points being situated at the germ end of the grain. A number of seeds of this character were planted in glass cases, but the resultant plants did not show any rust. If later experiments should confirm this possible mode of rust propagation, new light may be thrown on the entire rust problem, and the importance of proper seed selection would be shown.

Suggestions are given as to precautionary measures to be taken by farmers in order that the amount of rust may be reduced as much as possible. These include the thorough drainage of fields, the early and even maturity of the crop, thorough preparation of the soil and the use of clean seed, the selection of seed of pure varieties, treatment for prevention of smut so as to insure healthy plants if possible, keeping down weeds and volunteer plants which may carry the rust, destruction of all barberry shrubs, thorough grading of seed grain, and the rotation of crops.

**Plant diseases**, J. J. THORNER (*Arizona Sta. Rpt. 1905*, pp. 21, 22).—Brief notes are given on the alfalfa leaf spot (*Pseudopeziza medicaginis*) and the common grain rust (*Puccinia graminis*).

**Notes on Puccinia graminis**, J. JOANNIDES (*Trans. and Proc. Bot. Soc. Edinb.*, 23 (1905), pt. 1, pp. 63-67).—The author records observations on the occurrence of *Puccinia graminis* in Egypt and describes the continued existence of the rust during several years without the usual presence in the life cycle of the teleutospore condition and the subsequent acridal stage on the barberry.

**Culture experiments with rust fungi**, H. KLEBAHN (*Ztschr. Pflanzenkrank.*, 15 (1905), No. 2, pp. 65-108, pl. 1, figs. 4).—Notes are given on experiments carried on by the author during 1903 and 1904 with some 30 species of rust fungi.

Among the data given are special references to the wintering of *Puccinia dispersa*; the specialization of *P. digraphidis*; the alternate hosts of *P. stipa*; the specialization of *P. caricis*; notes on *P. polygoni amphibii*, *P. violae*, etc.; a new form of *Uromyces dactylidis*; the specialization of *U. scirpi*; notes on *Gymnosporangium clavariaeforme* and *G. juniperinum*; the relationship between *Ochrospora sorbi* and *Neidium leucospermum*; infection experiments with *Cronartium rubicola* on white pine, etc.

**Helminthosporium gramineum and Pleospora trichostoma**, F. NOACK (*Ztschr. Pflanzenkrank.*, 15 (1905), No. 4, pp. 193-205, pl. 1).—A report is given of the investigations of the author on the possible relationship between these two species of fungi, and he agrees with Diedicke (E. S. R., 16, p. 64) in holding that *Pleospora trichostoma* is the perithecial form of *Helminthosporium gramineum*, the cause of the stripe disease of barley.

Investigations with *H. teres* and *H. avenae* have thus far failed to reveal their perithecial stage.

**The prevention of stinking smut of wheat and loose smut of oats**, W. T. SWINGLE (*U. S. Dept. Agr., Farmers' Bul. 250*, pp. 16, figs. 7).—The author describes means for the prevention of the stinking smut of wheat and loose smut of oats, the methods detailed being the treatment with sar, which consists of a mixture of sulphur, alkali, and resin; the bluestone or copper sulphate and lime treatment; formalin treatment; and hot-water treatment. Directions are given for the use of these fungicides and for the handling of the grain after treatment.

**The smut of wheat**, C. MACÍAS (*Com. Par. Agr. [Mexico], Circ. 27*, pp. 4).—A brief account is given of smut of wheat, with directions for its prevention.

**Disease resistance of potatoes**, W. STUART (*Vermont Sta. Bul. 122*, pp. 107-136, dgm. 4).—In previous publications (E. S. R., 17, pp. 262, 670) accounts are given of studies of disease resistance of potatoes. The present bulletin gives the results of investigations on the resistance of vines to blight and tubers to rot. Investigations

were also carried on upon the resistance of tubers to scab, but the results so far obtained are inconclusive.

More than 150 varieties of potatoes were brought together from Europe and this country and planted under identical conditions, some being planted in clay loam and others in sandy loam. Frequent observations were made as to the presence of diseases and the relative amount of infection. There was some evidence that some of the varieties on the sandy loam were more disposed to the early blight, due to *Alternaria solani*, than others. The same is true of resistance to tip burn.

The principal investigations, however, were in connection with the late blight (*Phytophthora infestans*). This disease made its appearance about August 10 on Delaware and Green Mountain varieties, spreading slowly, the weather conditions during August not being propitious for its rapid development. The results of the investigations of the foliage are tabulated, from which it appears that a marked difference was to be observed in varieties. The resistance that is claimed for *Solanum commersonii* to late blight was found to be unwarranted under the conditions of the experiments.

In connection with the investigations on the resistance to potato rot a careful examination was made of all tubers as soon after digging as possible, and a list of the American varieties showing the greatest resistance to rot on the sandy and the clay loams is given. Keeper, American Wonder, Dakota Red, Doe Pride, and Late Blightless were the most resistant in both sandy loam and clay loam. The comparative rot resistance of European and American varieties is discussed, and it was found that on both sandy and clay loam the Dutch, German, and English-Scotch varieties showed much less rot than did the French and American varieties. While disease resistance is important, the commercial standards of this country favor qualities in which the German and Dutch varieties are inferior to the American varieties, and at present the writer does not feel warranted in recommending them to American growers.

The relative susceptibility of varieties which form their tubers deep or shallow was investigated, it having been claimed that those forming their tubers near the surface are more subject to rot than others, and while some differences might be noted, yet in both classes of soil about the same proportion of each was affected.

**Potato diseases and their remedies**, L. R. JONES and W. J. MORSE (*Vermont Sta. Rpt. 1905*, pp. 272-291).—In continuation of investigations reported in a previous publication of the station (E. S. R., 17, p. 261) accounts are given of spraying experiments, relation of date of digging to development of potato rot, relation of storage conditions to development of rot in potatoes, studies regarding the time and method of tuber infection by the rot fungus, and gaseous disinfection for potato scab.

The spraying experiments, which were conducted for the prevention of both late blight and rot, were carried on in the field. Bordeaux mixture, consisting of 6 lbs. of copper sulphate, 4 lbs. of lime, and 40 gal. of water, with the addition of  $\frac{1}{2}$  lb. of Paris green, was employed, 2 applications of the mixture being given the plants on August 2 and 21, respectively. At the expiration of the season the tubers were dug, and the gain at the rate of 161 bu. per acre is attributed to the application of the fungicide. The authors present in tabular form the gains from the use of Bordeaux mixture on late potatoes, covering experiments for the past 15 years in which the average gain for that period is 119 bu. per acre due to the treatment.

In a previous report (E. S. R., 14, p. 1084) the authors called attention to the method by which the spores of the fungus are carried from the leaves to the tubers, and suggested spraying the soil with Bordeaux mixture for preventing this infection. The previous trials were repeated in 1905 with good results, and the investigations show that not only does the disease pass from the leaf to the tuber, but the main channel is through the soil rather than through the stem. Spraying experiments for the control of the early blight showed the effect of thorough application of the fungicide,

the increased yield being attributed to the beneficial effects of the Bordeaux mixture, not only in checking the development of the fungus, but in deterring insect attacks.

In investigations on the relation of the date of digging to the development of the potato rot, results quite different from those previously reported (E. S. R., 17, p. 261) were obtained. In 1905 there was a greater loss from later digging than from earlier, and this is at variance with the previous rule laid down that digging should be deferred as long as possible where the rot is expected. In the authors' opinion this rule will have to be modified by making an exception of heavy wet soils during wet seasons.

Experiments were carried on to test the effect of liming, disinfection with formalin, sun-drying the tubers, and the temperature of storage on the development of rot in potatoes. It was found that instead of being an advantage in the preservation of tubers, the application of lime actually favored the development of rot. Disinfecting with formalin was without any material effect in checking it. In testing the relation of moisture to the development of rot it was found that potatoes exposed as much as practicable to sun and air prior to storage are less subject to rot than those stored immediately. The various temperatures of storage investigated were 40, 53, and 70°, and the greatest proportion of the crop saved was at the lowest temperature.

In studying the time and method of tuber infection different lots were subjected to different treatments. One lot was exposed for 36 hours to infection from blighting tubers immediately after digging, a second lot was not artificially infected but kept moist for 36 hours, and a third lot was stored without treatment immediately after digging. The relative loss was 92 per cent where the tubers were infected and not washed, 100 per cent where infected and washed, 77 per cent where not infected but kept moist for 36 hours, and 54 per cent where stored at once without any treatment. Concerning the possibility of spread in the storage cellar, it was found that spores may be produced in storage, and that well ripened sound tubers were readily inoculated with the fungus spores. From this it appears that there is no doubt as to the possibility of infection of tubers in storage.

In continuation of trials of gaseous disinfection for potato scab (E. S. R., 17, p. 261), the authors tested the relative value of gas treatment as compared with soaking seed for disinfection against scab, and also the merits of different ways of generating the gas. All the methods of disinfection showed marked gains in smooth tubers, but none of them gave a crop wholly free from scab. The average results obtained with the vapor treatments were better than those secured where the seed tubers were soaked in formalin solution, and the authors are led to recommend treatment of seed tubers with formalin gas by the permanganate method without the addition of steam. The cost of this treatment would be approximately \$1.50 per 1,000 cu. ft., and this method is recommended only for those seed potato specialists who may wish to disinfect large quantities of tubers.

**Concerning disease resistance of potatoes**, L. R. JONES (*Vermont Sta. Rpt. 1905, pp. 264-267*).—A brief account is given of investigations carried on by the author in connection with the Bureau of Plant Industry of this Department regarding the resistance of potatoes to various diseases, a preliminary report on which has already been issued (E. S. R., 17, p. 60).

**The potato leaf curl** (*Jour. Bd. Agr. [London], 12 (1905), No. 8, pp. 476-478, fig. 1*).—A description is given of the potato leaf curl or early blight (*Macrosporium solani*), and its occurrence is noted on *Solanum commersoni* grown at Kew.

**Sal Bordeaux for potato blight**, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 126, pp. 34, 35*).—In a previous publication of the station (E. S. R., 16, p. 1093) it was shown that dry Bordeaux as a fungicide was inferior to Bordeaux mixture as usually applied.

In 1905 an experiment was carried on to test the value of a dust spray known as **Sal Bordeaux**. This consists of equal parts of lime and exceedingly finely ground

copper sulphate, and it is applied as a dust on the theory that as soon as this dust becomes moist, from dew or otherwise, the regular Bordeaux mixture in concentrated form will be produced on the foliage. A number of plats received treatment with this fungicide at the rate of 3, 6, and 10 lbs. per acre. There was no blight on either the treated or untreated plats, so the results are considered inconclusive, and it is planned to repeat the experiment in 1906.

In connection with these experiments Paris green was used to prevent the ravages of bugs, and where it was applied in connection with the dry powder it was not as efficient as where the insecticide was administered in the form of a spray.

**Further experience in asparagus rust control,** R. E. SMITH (*California Sta. Bul.* 172, pp. 21, figs. 7).—In continuation of experiments previously reported (*E. S. R.*, 16, p. 66; 17, p. 48), the author gives an account of experiments carried on in California and elsewhere to control the asparagus rust, the principal information in the present publication being based on the results of practical work of various growers, especially observations made in connection with a ranch at Milpitas, Cal.

At this ranch the asparagus cutting was stopped about the first of July, and the rust was less abundant than usual on the uncut tops, but developed very vigorously after the beds grew up. An especial effort was made to keep down the wild growth about the edges of the field, which had in previous years caused a large amount of infection. After the end of the cutting season and the usual plowing and cultivation, the field was irrigated in order to start as vigorous a growth as possible. About August 1 heavy dews occurred, and the first application of sulphur was made. A special form of apparatus was employed, and sublimed sulphur at the rate of about 100 lbs. per acre was applied. Three weeks later a second application was made, and a third was given after a second interval of about 3 weeks.

The results of the treatment were quite apparent from the condition of the treated field. All untreated fields in the neighborhood were badly rusted in September and the tops were black and dead in October, while the field receiving the sulphur made a fine growth and the plants remained green until the normal end of the season. The cost of the treatment was at the rate of \$6 per acre for the season's work on 75 acres, and from the experience obtained it was thought possible to reduce this cost to about \$4 per acre for future treatments.

Other growers in the same locality applied sulphur to asparagus, and the results obtained were in proportion to the efficiency of the application. Near Sacramento attempts were made to control the rust with liquid sprays, and where Bordeaux mixture alone was used the effect on the rust was very slight. When sulphur was used in connection with the sprays, much better results were obtained, and based upon the trials of a number of growers, the following treatment has been adopted for future use: Three weeks after cutting, the plants are to be sprayed with whale-oil soap and water, followed by a dusting of sulphur at the rate of about 150 lbs. per acre. One month later sulphur is dusted over the plants at the rate of about 200 lbs. per acre, the applications to be made on dewy mornings.

The author cites illustrations of the use of sulphur for the control of the asparagus rust in other localities in California and also in South Carolina, where the treatment proved eminently successful.

In applying the sulphur the chief requisite is to scatter it so that it will cover all the growth in a dusty, smoky cloud. Experiments with ground and sublimed sulphur and flowers of sulphur showed that when all things are considered the flowers of sulphur is the most satisfactory and economical.

In conclusion the author states that in treating asparagus it is necessary to get a good coating of sulphur on the tops just before the rust is due to appear. A second application should be made 1 month later, and a third after another interval of about 4 weeks. Where young beds of asparagus are to be protected from rust, the author recommends a special form of treatment, which consists of spraying the

plants with whale-oil soap, to be followed by an application of sulphur, scattered by hand.

**White rust of cabbages** (*Jour. Bd. Agr. [London]*, 12 (1905), No. 8, pp. 480, 481, fig. 1).—A brief account is given of the occurrence of *Cystopus candidus* on cabbages. As the white rust most frequently occurs on shepherd's purse, it is recommended that all weeds of this kind should be destroyed in the vicinity of other crops that are liable to be infected by the fungus.

**Tomato diseases in California**, R. E. SMITH (*California Sta. Bul.* 175, pp. 16, figs. 8).—A preliminary report is given on the cause, nature, and possible means of prevention of some diseases of the tomato which have become exceedingly destructive in parts of California, and the further investigation of which is to be prosecuted in connection with the work of the new pathological laboratory for southern California.

The diseases described are the damping-off, which is due to one or more species of fungi, the summer blight, which is attributed to attacks of an undetermined species of *Fusarium*, and the winter blight, which is caused by the fungus *Phytophthora infestans*. For the damping-off, which is most prevalent in seed beds, the use of fresh earth, thorough ventilation, and the avoidance of overcrowding the plants are recommended as precautionary measures, and spraying with Bordeaux mixture, followed by sprinkling with sulphur, is advised where the disease has become established.

For the summer blight, which is due to a soil fungus, the only recommendation that can be made at present is planting healthy plants in new soil. Applications of lime, sulphur, etc., to the soil may be tried, but the effect of such treatment has not yet been demonstrated. Spraying can probably be of no use in connection with this disease. For the prevention of the winter blight, which occurs only after heavy rains or heavy fogs and dews, and in California affects only the winter crop of tomatoes, spraying after every rain with Bordeaux mixture is recommended.

**A *Fusarium* disease of tomatoes**, E. VON OVEN (*Landw. Jahrb.*, 34 (1905), No. 3-4, pp. 489-520, pls. 2, fig. 1; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 15-16, pp. 491, 492).—In 1901 and again in 1904 there appeared on tomatoes in the vicinity of Berlin a disease that became epidemic, causing considerable losses of the fruit.

Upon the blossom end of both green and ripe fruit appeared black spots that enlarged, and, through the softening of the underlying tissues, gave a wrinkled appearance to the fruit, which finally became a dried mummified mass. An investigation of the material showed there was a fungus in the tissues, and also abundant bacteria. Subsequent studies seemed to show that the bacteria were of secondary importance, finding entrance only after the destruction had been begun by the fungus.

The cause of the disease is said to be a species of *Fusarium*. The fungus appears to be usually a wound parasite, under normal conditions not being able to penetrate the epidermis of the fruit, but when especially abundant and vigorous in growth it seems to cause infection.

The author describes the results of inoculation experiments with the organism, which seems to be an exceedingly variable one, and which survives the winter in the numerous sclerotia formed in the mummy fruits. The fungus is described as a new species, with the name *Fusarium erubescens*, and it is critically compared with several other species of *Fusarium*.

Experiments have shown that weak solutions of Bordeaux mixture have little effect in checking the growth of the fungus. Therefore it is suggested that tomatoes should be sprayed with strong solutions of Bordeaux mixture as soon as the disease makes its appearance.

**Bacterial disease of tomatoes** (*Bd. Agr. and Fisheries [London]*, Leaflet 152, pp. 2, fig. 1).—A description is given of a bacterial disease of tomatoes that has been

known as occurring in France for a considerable time, where it has assumed the proportions of a destructive epidemic. It has been recently reported in several widely separated localities in England, on which account attention is drawn to it.

The symptoms of the disease are said to be very marked and can not be confounded with those of any other tomato disease at present known. When the tomato is about the size of a marble a minute black patch appears at the base of the style. This patch gradually increases in size, retaining a circular outline, until eventually the entire fruit is reduced to a blackish, soft, decayed mass.

Experiments have shown that infection takes place during the flowering stage and that the bacteria causing the disease are deposited on the stigma by flies visiting the flowers.

The stigma seems to be the only vulnerable part under ordinary conditions, but if bacteria from a diseased fruit are introduced into the flesh of a healthy tomato, infection follows.

The disease does not appear to be influenced to any extent by the forcing methods commonly followed, as it has been observed in houses where the temperature was kept comparatively low.

When the disease appears all diseased fruit should be removed as quickly as possible, and insects should be excluded by using insecticides. Where this is done, artificial pollination will be necessary.

**The blight canker of apple trees**, H. H. WHETZEL (*New York Cornell Sta. Bul.* 236, pp. 101-138, figs. 36).—A description is given of a form of apple-tree canker which is due to the same cause as that which produces the bacterial or fire blight of the pear. It seems to be favored by rapid growth of the trees, and the points of inoculation are water sprouts, wounds, and possibly the flowers. After reviewing the different kinds of cankers that have been described as occurring on apple trees, the author gives the distinguishing characters and appearance of the canker treated in this bulletin, which is due to *Bacillus amylovorus*.

These cankers occur most frequently on the bodies and limbs of young trees, and the diseased areas are sunken and smooth, covered with a brown surface, but not showing any pimples or fungus fruit bodies, which characterize some of the other forms of fruit-tree canker. The effect of the disease on the tree is to lower its vitality by cutting off the food supply to the roots and indirectly reducing the flow of sap to the branches and leaves.

Inoculation experiments have shown that the disease can be readily caused through wounds. As preventive measures the author recommends the burning of all dead limbs and trees as promptly as possible and cutting out and burning every trace of twig blight on both apple and pear trees as soon as detected. When pruning, all cut surfaces should be treated with corrosive sublimate or copper sulphate solution. Water sprouts should be cleaned from the trees, and the excessive use of nitrogenous fertilizers should be avoided. When possible the planting of varieties known to be resistant to the disease is recommended. Wolf River and Talman Sweet appear to be quite resistant, while Baldwin and Ben Davis suffer severely. In order to prevent the spread of the disease the author suggests an early spring treatment with lime-sulphur wash.

Notes are given on the distribution and severity of the disease throughout New York, and a detailed account is given of the identity of the organism, and notes on its morphology, cultural relation, etc. A bibliography of the publications relating to this disease completes the bulletin.

**A fungus disease of the mandarin orange**, P. A. SACCARDO (*Separate from Ann. Mycol.*, pp. 3; *abs. in Ztschr. Pflanzenkrank.*, 15 (1905), No. 3, p. 175).—The author states that mandarin oranges were noticed in Naples that showed dark spots on the rind, the spots later becoming confluent.

Upon examination the rind was found matted with mycelium which when old became of a dark violet color. When placed in a moist chamber there soon developed on the rind violet black hyphae and conidiophores that characterize *Alternaria tenuis*, but the fungus differed in some respects from this species. The author has described it as a form of the above species, naming it *A. tenuis chalaroides*.

**A disease of bananas in Central America**, H. PITTIER DE FABREGA (*Jour. Agr. Trop.*, 5 (1905), No. 54, pp. 379, 380).—A brief account is given of a disease of bananas, the origin of which is in doubt, but which has caused the destruction of hundreds of hectares of plants in Costa Rica and Panama. The author holds that the disease is due to faulty drainage, the soil having been saturated by heavy rains and lacking cultivation.

**The American gooseberry mildew**, J. ERIKSSON (*K. Landtbr. Akad. Handl. och Tidskr.*, 44 (1905), No. 4-5, pp. 273-288).—The author describes *Sphaerotheca mors-uvæ*, which is said to have first appeared in Sweden in 1902 and in Ireland in 1900, in Russia in 1901, and in Denmark in 1904.

An account is given of the distribution of the fungus in the United States, its life history, and methods of combating it. Among the protective measures recommended are the planting of healthy stocks, early destruction of badly affected bushes, and spraying the bushes and ground with potassium sulphid (30 gm. to 10 liters of water). When bushes are only slightly affected the diseased parts should be cut off and burned in the fall and the bushes sprayed early in the spring before the leaf buds appear. The spraying should be repeated every 8 to 14 days until the berries have attained about half their mature size.—F. W. WOLL.

**Black blight in Granada**, R. D. ANSTEAD (*Agr. News [Barbados]*, 4 (1905), No. 96, p. 394).—In a report to the Agricultural Committee of Granada, the author deals with the nature and control of the black blight that is prevalent in that island, attacking mango, bread fruit, sapodilla, guava, and rose apple trees. The blight is due to a species of *Capnodium*, which follows the presence of a number of scale insects.

For the prevention of the disease the author recommends cultivation of the plants, clean culture, and the use of insecticides against the scale insects.

**Gray blight of tea**, T. PERCH (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 5, pp. 630, 631).—The author gives a note on the gray blight of tea, which is attributed to the fungus *Pestalozzia guepini*, and calls attention to the fact that spores indistinguishable from those producing the gray blight are formed on rose leaves attacked by *Actinonema rosæ* when kept in a moist chamber for some days. This form has been called *P. suffocata*, but the author believes the differences are so slight as to indicate the possible identity of this species with the one above.

The gray patches on tea leaves are said to be well known, but in some cases the fungus attacks the leaf stalk at the junction of the stem, in which case the leaf turns brown, falling from the bush before producing any indications of the disease on the leaf. The stem of the bush may also be attacked, the fungus entering the young shoot at the cut end left in gathering the tea, in which case the young shoot is killed to the base. It also occurs on stems an inch or more in diameter, forming a kind of canker. A similar fungus is said to attack *Ilex brasiliensis*, causing slight damage to the leaves, but the plants in a short time recover from the attack.

**The bud rot of the cocoanut palm** (*West Indian Bul.*, 6 (1905), No. 3, pp. 307-321; noted in *Agr. News [Barbados]*, 4 (1905), No. 95, pp. 369, 370).—Mention has already been made of the occurrence in various parts of the West Indies of a serious disease of cocoanut palm known as the bud rot. This has recently become prominent in Trinidad, where one plantation reports the loss of 2,000 trees in 6 months.

The cause of the disease has been attributed to the fungus *Pestalozzia palmarum*, but recent investigations (E. S. R., 17, p. 158) seem to indicate that bacteria play an important part.

It is said that probably no remedial measures will be found effective in the case of palms already seriously attacked, but to prevent the further spread of the disease all affected palms should be cut down and burned or buried with lime. Experiments in Jamaica have shown that spraying with Bordeaux mixture on the first indication of the disease is somewhat effectual. As the disease is of a virulent character, energetic efforts are recommended to stamp it out.

A green-skinned variety of cocoanut in Jamaica is said to be less liable to bud rot than the yellowish and reddish varieties commonly grown, and if this should be confirmed it may be possible to establish a race of cocoanuts resistant to disease.

**Cacao disease in Ceylon** (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 2, pp. 293-296).—The cacao trees in Ceylon are subject to a serious disease, which finds favorable conditions for its spread in dense shade and abundance of moisture commonly found on cacao plantations.

The disease, which is of fungus origin, attacks both fruit and stems. The pods become dark brown or black, and unless controlled the disease spreads rapidly. The disease can be restrained by collecting and destroying the diseased pods at frequent intervals, or by spraying with Bordeaux mixture. In addition the shade should be removed to some extent and the diseased tissues of the stems collected and burned.

In 1902, 96 per cent of the trees and 14 to 62 per cent of the pods of a plantation were attacked by the fungus. The preventive measures described above were begun in 1902 and within 6 months an improvement was noted. In 1904 less than 4 per cent of the fruit was attacked and the yield increased from 0.83 cwt. per acre in 1902 to over 2 cwt. in 1904.

**Canker of rubber**, T. PETCH (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 2, p. 298).—In a report on the canker of *Hevea brasiliensis* mention is made of the fact that a large portion of the fruit did not ripen and split in the normal way, but remained on the tree and blackened or fell off without splitting.

An examination showed that this condition is due to a parasitic fungus similar to, if not identical with, that which causes the decay of cacao pods, which is generally attributed to *Phytophthora omniura* and *Colletotrichum incarnatum*, the first of which is the more destructive. The *Hevea* fruits examined were all attacked by a species of *Phytophthora* which permeates the soft outer tissues of the fruits, causing the seeds to dry up. All diseased fruit should be collected and burned as a precautionary measure.

**A disease of *Hevea* seedlings**, T. PETCH (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 24 (1905), No. 12, p. 138).—A report is given of leaves of *Hevea* seedlings being attacked by a species of *Helminthosporium*.

The leaves were studded with circular, semi-transparent spots, each surrounded by a brown layer. It is thought probable that the spots are due to insect punctures and that the fungus gains access to the tissues through these injuries. As a consequence of this discovery a number of nurseries of this species of rubber were examined without discovering much disease, but there were found commonly present injuries that seemed to be due to fungi, the most common of which was *Periconia pycnospora*. It is believed that the fungi were present as a result of mechanical injury, which in many instances is attributed to the burning of the leaves by light shining through globules of water collected on the foliage.

**The destruction of Siberian firs in Adlisberg**, H. C. SCHELLENBERG (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw.*, 8 (1905), No. 3, pp. 269-286, pl. 1).—In 1901 the author examined a plantation of Siberian firs that was about 30 years old and found many of the trees suffering from the attacks of some fungus. Upon closer investigation the bark was found thickly studded with the small orange-yellow fruiting bodies of *Dasyscypha calyciformis*, and where these bodies were abundant the

bark was dead and of a reddish color. The trees in general appeared unhealthy and many were dead.

Subsequently studies were made of the fungus, and comparisons are drawn between this and allied species. The development and life history of the parasite are described, after which notes are given on inoculation experiments carried on in the forest, the amount of injury caused, etc.

**Root rot of logwood trees** (*Agr. News* [Barbados], 4 (1905), No. 96, p. 389).—This disease, which was previously described (E. S. R., 14, p. 882), causes the destruction of trees in considerable number through the presence of a mycelium invading the roots and spreading upward into the trunk, between the bark and the wood. Although the fruiting organs of the fungus have not been discovered, it is believed to be a hymenomycete.

The disease is found in trees growing in different kinds of soils and under varying climatic conditions, and has been recently reported as spreading rapidly in Jamaica. It is contagious, spreading through the soil, and to prevent its further spread it is recommended that trenches 3 ft. deep be dug about the diseased area, when confined to definite patches. Where it is widely disseminated the clearing of the infested tract and cultivation with other crops are recommended.

**Some Indian forest fungi**, E. J. BUTLER (*Indian Forester*, 31 (1905), No. 10, pp. 548-556, figs. 3).—After discussing fungus diseases in general, the author describes the attacks of *Chrysomya himalense* on rhododendrons and different forms of *Gymnosporangium cunninghamianum*, the æcidial form of which occurs on *Pyrus pashia* and the teleuto form on cypress.

**Some rose diseases**, E. FOEX (*Prog. Agr. et Vit. (Ed. l'Est)*, 26 (1905), No. 48, pp. 616-619, pl. 1).—The author describes the rose rust, due to *Phragmidium subcorticium*, the rose mildew (*Sphaerotheca pannosa*), and the attacks of *Marsonia rosa*, which causes the premature falling of the leaves.

For the control of the mildew the author recommends spraying with a mixture of carbonate of soda 1.5 kg., Norwegian tar 0.5 kg., and water 100 kg.

**North American salvia rusts**, E. W. D. HOLWAY (*Jour. Mycol.*, 11 (1905), No. 78, pp. 156-158).—Technical descriptions are given of a number of species of rusts that are known to attack various species of salvia, and *Puccinia infrequens*, *P. badia*, and *P. nerea* are described as new species.

**A new orchid disease**, G. MASSEE (*Gard. Chron.*, 3. ser., 38 (1905), No. 973, pp. 153, 154, fig. 1).—A description is given of a recently recognized disease of *Oncidium*, which is attributed to *Hemileia americana* n. sp.

This fungus, which is closely allied to that causing the most destructive coffee disease, threatens to become a serious pest in orchid culture if it once becomes established. The fungus forms bright orange, powdery-looking patches of various sizes on the under surface of the leaf, with corresponding areas of a sickly yellowish-green color on the upper surface. On account of the threatened seriousness of this disease, the prompt destruction of every leaf showing the symptoms above indicated is recommended.

**An orchid disease**, H. KLITZING (*Gard. Chron.*, 3. ser., 38 (1905), No. 980, p. 259).—A description is given of *Glaeosporium beyrodtii*, a new species which appears in dense masses on both sides of the leaves of *Vanda carulea*. The spots sometimes run together, forming dark blotches, and finally bring about the destruction of the entire plant. The fungus is briefly characterized.

**The action of copper salts on plants**, F. PORCHET and E. CHUARD (*Bul. Murith. Soc. Valais. Sci. Nat.*, 1904, No. 33, pp. 204-210, pl. 1).—This bulletin, which was issued in 1905, gives an account of experiments which have been carried on at the Viticultural Station of Lausanne since 1886 to test the effect of copper compounds on plants, especially the practical effect in reducing disease, and the effect of fungicides on wines made from sprayed grapes.

The physiological effect of fungicides on the plants themselves, particularly with reference to fruit maturing, has also been determined. The investigations showed that treating vines with copper solutions resulted in a stimulation of growth, through the absorption of minute traces of copper, and the ripening period of the grapes was also accelerated.

To determine the penetration of copper into plant tissues an experiment was inaugurated in the spring of 1903 in which different lots of grape cuttings were potted in a peaty leaf mold and the different pots given varying amounts of copper, iron, magnesium, and cadmium salts in solution, the concentrations varying from 0.001 to 1 per cent. In 10 days the lots receiving the weaker solutions of copper began to force their buds. Eleven days later those which had received magnesium sulphate had 4 leaves, and the buds on the cuttings receiving 0.01 and 0.001 per cent copper sulphate were bursting. All others showed no growth.

At the end of 33 days all buds had burst except those receiving iron sulphate, and these were more than 2 months in developing. In the autumn it was observed that the leaves remained on the treated vines long after the check lots had lost their leaves, and the cuttings treated with magnesium sulphate and iron sulphate lost their leaves before those which received the copper sulphate solution. These retained their foliage late into the fall, ultimately losing them in direct proportion to the strength of solution with which they had been treated.

The quantity of copper in the different lots was determined late in the autumn, and it ranged from 0.0133 gram of copper per 100 gm. of dry weight for the lot receiving a 1 per cent solution to a trace in the lot receiving 0.01 per cent, and not even a trace where the more dilute solutions were used.

Recognizing the corrosive action of copper sulphate on the delicate roots formed from cuttings, this feature was investigated, and it was found that the humus in the pots had acted on the copper, causing it to lose its toxic effect upon the root tissues.

**The adulteration of copper sulphate** (*Jour. Bd. Agr. [London], 12 (1905), No. 9, pp. 542, 543*).—On account of the extensive use of copper sulphate as a fungicide and the corrosive effect of some impurities, the writer suggests that in purchasing this material demand should be made for a product of 98 per cent purity. This is practically a pure copper sulphate and is without the corrosive effect that is observed in some of the adulterated specimens.

The results of the analysis of an adulterated sample show that it contained 17.6 per cent crystallized copper sulphate and 82.4 per cent crystallized iron sulphate. As an easy test for the presence of iron in copper sulphate the writer suggests dissolving a little in water and adding ammonia with constant stirring until a liquid of a deep blue color is formed. If iron is present in any quantity it will be shown by the occurrence of brown flocculent masses floating in the blue liquid.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Agricultural zoology**, G. GUÉNAUX (*Zoologie Agricole. Paris: J. B. Baillière & Co., 1905, pp. XII + 563, figs. 168*).—The present volume includes a general discussion of the importance from an agricultural standpoint and the use of farm animals, together with an account of the habits and economic relations of birds, reptiles, amphibians, and small mammals. Particular attention is given to the feeding habits of the various species discussed.

**Protection of birds which are beneficial to agriculture** (*Jour. Agr. Prat., n. ser., 10 (1905), No. 52, pp. 816-818*).—An international convention was held in Paris on December 6, 1905, at which time various European countries were represented, including France, Germany, Austria-Hungary, Belgium, Spain, Greece, Sweden, Switzerland, etc. The purpose of this convention was to adopt a uniform method of procedure regarding the protection of beneficial birds.

At this convention 16 articles or resolutions were adopted and some of the more important points mentioned in these resolutions may be briefly stated in this connection. Insectivorous birds, of which a list is given and to which additions may be made as more knowledge is gained concerning the feeding habits of these birds, are recommended for absolute protection as well as their nests and eggs. More stringent legislation is recommended for preventing the destruction of nests and eggs and the use of traps, cages, nets, and other devices for capturing birds. The proprietors of vineyards or gardens are to be granted the privilege of destroying birds in case they should become injurious on the premises in question. A list is also given of injurious birds.

**Special report on the decrease of certain birds and its causes with suggestions for bird protection**, E. II. FORBUSH (*Agr. of Mass.*, 52 (1904), pp. 429-543, pls. 2).—An elaborate historical account is given of the former prevalence of birds in Massachusetts and neighboring States and the decrease in numbers of these birds due to various causes.

Among the agencies which may affect the destruction of birds the author enumerates the unfavorable weather of 1903-4, the destruction of birds by sportsmen, bird shooters and trappers, market hunters, boy gunners, and egg collectors. Apparently six species of game birds and water fowl have disappeared in Massachusetts within historical times and shore birds are estimated to have decreased in numbers to the extent of 75 per cent. Swallows, night hawks, eagles, great blue herons, house wren, red-headed woodpecker, and various other species of similar birds are on the decrease.

Notes are given on the natural enemies of birds, especially cats and English sparrows. In order to protect birds from further unnecessary depredations it is suggested that more attention be given in the schools to the economic value of birds and the desirability of protecting them.

**Animal and insect pests**, E. WRIGHT (*Queensland Agr. Jour.*, 16 (1905), No. 1, pp. 67-70).—The flying fox is considered as one of the most important fruit pests along the eastern coast of Queensland. Notes are also given on certain birds which are injurious to fruits as well as on the fruit fly and other insect pests.

**Entomology with special reference to its biological and economic aspects**, J. W. FOLSOM (*Philadelphia: P. Blakiston's Son & Co.*, 1906, pp. VII + 485, pls. 5, figs. 300).—According to the author this volume is intended for the student and general reader, and was written to cover as fully as possible within the limits of the book the biological aspects of insects.

The subject-matter is arranged under the heads, classification; anatomy and physiology; development; adaptations of aquatic insects; color and adaptive coloration; origin of adaptations; insects in relation to plants, animals, and man; insect behavior; and distribution. A classified bibliography of important entomological literature is also presented (pp. 409-466). The literature of economic entomology is discussed. One of the most valuable features of the book is the discussion of the economic relations of insects.

**Catalogue of publications relating to entomology in the library of the U. S. Department of Agriculture** (*U. S. Dept. Agr., Library Bul.* 55, pp. 562).—This bulletin contains a classified list of 5,600 publications relating to entomology in the library of the Department. The titles are grouped under general entomology, economic entomology, faunas, and various orders of insects, Myriapods, and Arachnida. A list of serial publications relating to entomology is also given and the bulletin is provided with an index to insect families and authors.

**Insects of the year**, W. STUART (*Vermont Sta. Rpt.* 1905, pp. 309-314, figs. 2).—No serious outbreaks of injurious insects occurred during the season, but the usual number of requests were made concerning insect injuries of lesser importance.

Among the injurious species of which brief notes are given are woolly aphis, red-humped apple-worm, oyster-shell bark-louse, and apple-leaf miner.

**The periodical cicada in 1906**, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent. Circ. 74, pp. 5, figs. 3*).—During the present season two broods of the periodical cicada will reappear, one being a 17-year brood and distributed from Illinois to Massachusetts and southward to Georgia. The other is the 13-year brood and is distributed in North Carolina, Georgia, Alabama, and Tennessee. Brief notes are given on the damage done by this pest. The broods are expected to appear about the last week in May.

**Studies in grasshopper control**, J. S. HUNTER (*California Sta. Bul. 170, pp. 23, figs. 17*).—During 1904, grasshoppers were very injurious in the San Joaquin Valley, where they hatched out in April or earlier and appeared in large numbers early in May. Various crops are raised on the infested ground, but in one locality the grasshoppers were found very injurious in an area of about 2,000 acres devoted to alfalfa. The species concerned in this outbreak are *Cimopteleura melanopteleura*, *Melanoplus uniformis*, *M. devastator*, and *Ceduleonotus enigma*.

In combating grasshoppers it was found possible to destroy the young insects by burning the grass where the ground was fairly well covered. The winged form were also destroyed by the same means if the work was done during cool nights. Considerable success was had in poisoning grasshoppers, not by the Criddle mixture, which was unsatisfactory, but by the use of a poison bait which contained 5 lbs. of arsenic in 40 lbs. of bran moistened with 2 gal. of molasses. Hopperdozers could not be used as effectively in orchards as in alfalfa fields. Occasionally good results could be obtained by smoking the grasshoppers out of the fields. Near Newman the injurious species was *Melanoplus differentialis*. This pest defoliated vineyards and orchard trees, eating the fruit.

**The Hessian fly**, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 70, pp. 16, figs. 16*).—A general account is presented of this important insect of wheat with notes on its early history, appearance, stages, habits, distribution, food plants, and injuries.

There appears to be no variety of fly-proof wheat, although macaroni wheat is somewhat less injured than other kinds. The natural enemies of the pest are discussed, and notes are given on the various remedies which have been tried for this insect, late sowing, crop rotation, burning of stubble, destruction of volunteer wheat, use of fertilizers, preparation of the soil, and use of good seed. In preventing the attacks of the Hessian fly the author recommends that good seed should be sown in well-prepared soil after the larger part of the fall brood has made its appearance. In spring seeding it is believed that the earlier wheat is sown the less danger there will be from the Hessian fly.

**Some insects affecting the production of red clover seed**, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 69, pp. 9, figs. 8*).—Particular attention is given in this circular to the clover-flower midge and clover-seed chalcis.

It is believed that the clover-flower midge does not really infest the seed but lays its eggs in the ovaries before fertilization has taken place. The clover-seed chalcis, however, lives in the seeds only. No insects like bumblebees are able to fertilize clover which has been infested with the clover-flower midge. This insect is described in all its stages and notes are given on its life history. It has been reported as quite common in England and occurs in this country wherever clover is grown.

The best methods of controlling it consist in cutting clover not later than the second week in June in fields where clover is grown without much admixture of timothy. This operation seems to destroy the larvæ of the midge and also to hasten the second blooming so that the flowers are too far advanced for infestation by the midge. In cases where clover and timothy are grown mixed, the same results may be obtained by pasturing clover in the spring so as to delay the flowering period.

The clover-seed chalcis is also described and notes are given on its life history. This pest attacks the seed of red and crimson clover and also alfalfa. It is distributed also from New England to California on the west, and south to Mississippi. Insect enemies capable of controlling the pest are not known. Remedies recommended for the clover-flower midge might apply to this insect, and it is also suggested to destroy scattering heads of clover together with the chaff and stems after hulling.

**The clover root borer**, F. M. WEBSTER (*U. S. Dept. Agr., Burr. Ent. Circ. 67, pp. 5, figs. 4*).—This insect is a native of Europe and has become generally established in the eastern States. It attracted attention in 1878 in New York and has gradually spread toward the Mississippi River.

The insect is described in its various stages and notes are given on its life history and food plants. There appears to be but one annual generation. It feeds on red clover and alfalfa as well as other species of clover. Infested clover plants sooner or later die as a result of the attack of this insect. Apparently the only successful way of combating the pest is summer fallowing as soon as the hay crop is removed.

**The tobacco thrips and remedies to prevent "white veins" in wrapper tobacco**, W. A. HOOKER (*U. S. Dept. Agr., Burr. Ent. Circ. 68, pp. 5, figs. 2*).—*Euthrips nicotianæ* was described in September, 1905. The insect injures shade-grown cigar-wrapper tobacco in Florida, Georgia, and Texas.

The removal of the sap from the lateral veins of the leaves causes white streaks when the leaves are cured. This is objectionable from the standpoint of the cigar maker and reduces their value about 50 per cent. The adult insect appears to pass the winter in the tobacco fields. They deposit their eggs in the tissues of the stem and leaves and the young larvæ feed on the under surface of the leaves and the adults feed upon the upper surface. In combating this species clean cultivation is recommended. The pest appears in oats and it is urged that this crop be not planted in the vicinity of tobacco fields.

As an insecticide application the author recommends the use of kerosene emulsion according to the formula 2 gal. of kerosene, 1 gal. of water, and  $\frac{1}{2}$  lb. of hard soap diluted to make 10 gal. A number of applications should be made while the plants are in the seed bed and later in the field about two applications a week may be required. The expense of such an application does not exceed \$20 per acre.

**Pea and bean beetles** (*Bd. Agr. and Fisheries [London], Leaflet 150, pp. 4, figs. 2*).—Descriptive, economic, and biological notes are given on *Bruchus pisi* and *B. rufimanus*.

**The turnip mud-beetle**, R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 102-104, fig. 1*).—*Helophorus rugosus* is quite widely distributed throughout England and Scotland. It attacks turnips by eating the leaves and tunneling the leaf stalks and roots. The injury is done both by the beetle and larvæ. Rotation of crops is recommended in controlling this pest, together with the liberal use of fertilizers.

**The use of bisulphid of carbon against wireworms** (*Jour. Bd. Agr. [London], 12 (1905), No. 2, pp. 104, 105*).—It has been found that the character of the soil largely determines the rate at which the fumes of this gas diffuse from the point where it was injected into the soil. In using bisulphid of carbon against wireworms little benefit can be expected on very wet soils, and the application should be made before the damage from the wireworms is too far advanced, and moreover the bisulphid of carbon should not be allowed to come in contact with the roots of the plants.

**Report of the State nursery inspector**, H. T. FERNALD (*Agr. of Mass., 52 (1904), pp. 243-247*).—Of the pests which require the attention of the inspector in Massachusetts, San José scale, oyster-shell scale, gypsy moth, and brown-tail moth are the most important. Brief notes are also given on black knot and other fungus diseases.

**Report on work done in 1903-4 in the control of San José scale and other dangerous insect and fungus pests** (*West Virginia Sta.*, 1904, pp. 96, figs. 16).—An account of nursery inspection during the year under report is given by W. E. Rumsey (pp. 7-15).

A tabulated list of West Virginia nurseries is presented, with notes on their condition. The work along the line of orchard inspection is discussed by W. E. Rumsey and T. E. Brooks. This account includes a statement regarding the distribution of San José scale in country districts and in towns, spray mixtures for use in controlling this insect, and a brief résumé of the principal fruit sections of the State. The report also contains an account of spraying melons in the Ohio River Valley, by F. E. Brooks, and plant diseases of the State, by J. L. Sheldon.

**Report on work done in 1904-5 in the control of San José scale and other dangerous insect and fungus pests** (*West Virginia Sta.* [1905], pp. 60, pls. 7).—In the report for this year considerable attention is given to the grape curculio, which is discussed by F. E. Brooks. The same author also discusses nut weevils in West Virginia.

The report also contains a special report of the bacteriologist, J. L. Sheldon, on various plant diseases; potato blight, by A. L. Post; other investigations on potatoes, by T. C. Johnson; and a study of combined insecticides and fungicides, by B. H. Hite and C. H. Howard. Brief notes are also given as usual in these reports on nursery and orchard inspection.

**Some points in nursery inspection**, F. A. POPEHOE (*Industrialist*, 32 (1906), No. 18, pp. 275-279).—The San José scale was the chief cause of the present nursery inspection laws in Kansas. A brief account is given of the methods employed in inspecting the nurseries, with particular reference to the more serious insect and fungus diseases. It is believed that not all of these diseases are transmitted in nursery stock. Apple-tree borers are apparently seldom carried in young nursery stock.

**The plum curculio**, F. JOHNSON and A. A. GIRAULT (*U. S. Dept. Agr., Bur. Ent. Circ.* 73, pp. 10, figs. 5).—The life history and habits of this pest are described in detail.

The insect attacks plums, cherries, peaches, nectarines, apricots, apples, and pears, and sometimes feeds upon the foliage after the fruit has been harvested. The method of the attack upon various fruits is described and notes are given on the natural enemies of the pest. One of the most extensively applied remedies for the insects consists in the use of some form of jarring trap. This method has been widely adopted in plum and peach orchards in the South and has proved very satisfactory. The pest may be destroyed by thorough spraying with arsenicals. For this purpose arsenate of lead may be used at the rate of 2 lbs. to 50 gal. of water, or Paris green at the rate of 1 lb. to 150 to 200 gal. of water.

**The codling moth in Arizona**, J. J. THORNER (*Arizona Sta. Rpt.* 1905, p. 22).—The codling moth has been known in Arizona for 2 years and in infested districts causes wormy apples to the extent of 30 to 40 per cent. No hope is held out that this insect may be eradicated in Arizona, but it is believed that its presence will have an indirect benefit in forcing orchardists to spray their trees more thoroughly.

**Report of committee on gypsy moth, insects, and birds**, A. PRATT ET AL. (*Agr. of Mass.*, 52 (1904), pp. 217-239).—A brief review is presented of the condition of the infested region contrasting the conditions observed in 1899 and 1904 in various towns in the neighborhood of Boston. A few new colonies have appeared outside the area which was known to be infested in 1899. In general the insect has spread slowly in various directions and in the localities of long infestation the numbers of the pests have greatly increased.

**The brown-tail moth in Maine**, E. F. HITCHINGS (*Bul. Maine Dept. Agr.*, 4 (1905), No. 4, pp. 101-127, pls. 4).—A copy is presented of considerable correspondence relating to the prevalence of the brown-tail moth in Maine.

The Pomological Society of the State succeeded in getting an appropriation of \$5,000 for 1905 and 1906 for the purpose of combating the brown-tail moth. In accordance with the act passed by the legislature a State entomologist was appointed to devote his time to the suppression of this and other insect and fungus pests. A review is given of the present status of the brown-tail moth in Maine. In many localities rewards have been offered for the destruction of the nests of this insect, and data regarding the amounts of money thus expended are presented in a tabular form.

The life history of the brown-tail moth is described and notes are given on other insect pests, including apple aphid, woolly aphid, scurfy bark-louse, and strawberry weevil, as well as on nursery inspection.

**The goat moth and the wood leopard moth**, R. S. MACDOUGALL (*Jour. Bd. Agr. [London]*, 12 (1905), No. 2, pp. 115-118, fig. 1).—Notes are given on the habits and life history of *Cossus ligniperda* and *Zeuzera asculi*. Small branches infested with the leopard moth should be removed and burned, and the same remedies should be applied to trees infested with goat moth. The goat moth may be prevented to some extent from laying its eggs by painting the lower part of the tree with soft soap, kerosene, or some other substance obnoxious to the insect.

**Woolly aphid**, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, 13 (1905), pp. 407-409, figs. 4).—This pest is difficult to control on the more susceptible varieties of apples. A list is presented of apple varieties which appear to be more or less resistant to woolly aphid. The aerial form of the pest may be controlled by the use of kerosene emulsion or by fumigation with hydrocyanic-acid gas.

**Leaf hoppers and their natural enemies**, R. C. L. PERKINS and G. W. KIRKALDY (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul.* 1, pls. 9, pp. 267-479, pls. 12; 10, pp. 483-499, pls. 6; introduction, pp. XXXII+501-508, figs. 7).—In continuation of this series (*E. S. R.*, 17, p. 783) the general anatomical characters of leaf hoppers are described by G. W. Kirkaldy, in part 9, with notes on the rapidity of their multiplication, other points in their life history, and their classification. In the study of this group in the Hawaiian Islands and elsewhere various new species have been discovered and of many of these descriptions are given. Notes are also presented on the relations between leaf hoppers and ants. A bibliography of literature relating to leaf hoppers is appended to the bulletin.

Part 10 is supplementary to part 1 (*E. S. R.*, 17, p. 477), and deals with observations made in Australia and Fiji Islands and material collected in those countries. A number of new species of Dryinidae and Pipunculidae are described.

In the introduction by R. C. L. Perkins, which is the last part received, a general account is presented of the work done in Australia, Fiji Islands, and the United States, with particular reference to the methods of transporting and handling parasites and also to the effects of these parasites upon the leaf hoppers. A brief summary of the bulletin is added, together with an index.

**The pepper weevil**, A. MERAZ (*Com. Par. Agr. [Mexico]*, *Circ.* 33, pp. 4, fig. 1).—Peppers are subject to the attacks of *Anthonomus eugenii*. This pest was studied by the author, with particular reference to practical methods for controlling it.

It is recommended that peppers should not be planted on soil cultivated to Indian corn during the previous year. The selection of seeds from fruits which have resisted the attack of the insect is desirable on account of the fact that they possibly possess some resisting power. Infested fruits should be collected and destroyed as soon as they are recognized. Rotation of crops is also recommended. Some benefit may be derived on spraying with arsenicals, especially arsenate of lead.

**The habits, life history, and means of combating *Agrostis segetum*, K. ROSSIKOV** (*Truhai Byuro Ent. [St. Petersburg.], 6 (1905), No. 5, pp. 120, pls. 4, figs. 37*).—An elaborate review is presented of the appearance, distribution, and life history of this cutworm. The author discusses the number of generations, the egg, larva, and other stages of the pest. Attention is given also to its insect parasites belonging to various orders, with reference also to fungus and bacterial diseases. In the discussion of methods for controlling the pest the subject is discussed under different heads, according to the stage of the insect concerned.

**The larva of *Plodia interpunctella*, B. WAHL** (*Zschr. Landw. Versuchsw. Oesterr., 8 (1905), No. 10, pp. 950-954*).—This pest was found in fig coffee and also in a number of other food products. The systematic position of the moth is briefly outlined, and detailed notes are given on the external anatomy of the caterpillar, with particular reference to the number and location of the bristles.

**Parthenogenesis in *Otiorrhynchus turca*, A. A. SSILANTJEW** (*Zool. Anz., 29 (1905), No. 18, pp. 583-586, figs. 2*).—In studying this insect which has recently caused great damage to grapes in the region of the Black Sea, the author observed that no males were to be found. Observations along this line showed that females taken immediately after emergence and kept confined in glass jars during their whole life laid eggs which were perfectly fertile and developed into normal individuals.

**On the Cecidomyid forming the galls or pseudocones on *Pinus longifolia*, E. P. STEBBING** (*Indian Forester, 31 (1905), No. 8, pp. 429-434, pl. 1*).—For some time galls have been noticed on this pine tree which so closely resembled the cones as to be mistaken for them. When examined by the author they were found to be due to a species of Cecidomyia, which is briefly described. Notes are also given on a parasitic insect found upon the gall insect.

**A new enemy of the Douglas fir, R. S. MACDOUGALL** (*Jour. Bd. Agr. [London], 12 (1906), No. 10, pp. 615-621, figs. 4*).—*Megastigmus spermotrophus* was found infesting the seeds of Douglas fir.

This insect is described in its various stages. The eggs are laid in the young cones of the Douglas fir and each seed is infested by one larva. In preventing the destruction of cones by this pest it is recommended that after the seed is collected it should be subjected to treatment of bisulphid of carbon at the rate of 1 oz. for every 50 cu. ft. of air space.

**Notes on termites with special reference to the destruction of timber by *Calotermes brouni*, T. BROUN** (*New Zeal. Dept. Agr. Ann. Rpt., 13 (1905), pp. 430-436, pls. 2*).—It has been found that for railroad ties various woods may safely be used which would otherwise soon be destroyed by white ants. This is due to the fact that the ants are frightened away by the jar produced by passing trains.

*Calotermes brouni* is an exceedingly injurious species, and notes are given on its injury to various kinds of wood, especially Puriri and Kauri woods. The insect is described in its various stages.

**Spraying apples. Relative merits of liquid and dust applications, C. S. CRANDALL** (*Illinois Sta. Bul. 106, pp. 205-242, figs. 14*).—While a combination of Bordeaux mixture and arsenicals has long been known to give satisfactory results in the control of scab and some of the other common fungus diseases of apples, as well as codling moth and leaf-eating caterpillars, the method is somewhat extensive and various experiments have been made to test the economy of dust sprays.

The author's work along this line has been carried on for a period of 3 years, during which various plats of apple trees were sprayed or dusted from 3 to 8 times during the season, the first application being made just as the buds were opening. Particular attention was given during this series of experiments to the effect of treatment on apple scab, fruit blotch, codling moth, and curculio. It appears from these experiments that the pests just mentioned must be recognized as of a permanent nature and

that they require annual treatment in order to secure a good crop of clean fruit. The use of a dust spray considerably diminishes the cost and labor of spraying, but it is quite inefficient.

Trees sprayed with liquid Bordeaux mixture and Paris green retained their foliage through the season, while the foliage turned yellow and fell off from the trees treated with a dust mixture as readily as from the check trees. This loss of foliage is an important matter in the growth of the tree and indicates clearly that the dust method is not satisfactory. The dust spray is 52 per cent cheaper than the liquid spray but, according to the author, has no other advantages. It is, therefore, recommended that the orchardist spend his time and energy in perfecting his methods of preparation and application of Bordeaux mixtures combined with arsenicals.

In these experiments the formula used for the liquid Bordeaux mixture was 4 lbs. copper sulphate, 4 lbs. of lime,  $\frac{1}{2}$  lb. Paris green per 50 gal. of water, and a proprietary form of Bordeaux and Paris green was used for the purpose of comparison.

**Spraying**, G. F. WARREN (*New Jersey Stat. Bul.* 194, pp. 60).—The purpose of the author was to combine in the present bulletin in a convenient form the various recommendations which have been made by the station in previous publications regarding the control of insects and fungus diseases. The bulletin constitutes a convenient summary of information on this subject and contains an account of the purpose of spraying, the methods to be adopted in spraying various fruit and garden crops, a spray calendar, formulas for the preparation of the more important fungicides and insecticides, and a discussion of spray pumps.

**Spray calendar** (*Vermont Sta. Spec. Bul.*, Apr., 1906, folio).—Formulas are given for the preparation of lime-sulphur-salt wash, Paris green, Bordeaux mixture, Hellebore, and kerosene emulsion, and brief directions are given for the application of these remedies.

**The preparation of emulsions of crude petroleum**, T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 89, pp. 4).—The ordinary kerosene emulsion is not well adapted for use as a dip or hand treatment for animals, since the oil does not remain emulsified and is distributed unevenly on the surface of the body.

Beaumont oil has been found by the Bureau to be an effective dip for destroying cattle ticks. There are certain objections to its use, however, particularly an occasional injury to cattle. Experiments were therefore made to secure an emulsion which would remain uniform for an indefinite period. This was accomplished by employing a formula calling for 2 gal. crude petroleum,  $\frac{1}{2}$  gal. water, and  $\frac{1}{2}$  lb. hard soap. The soap is dissolved in hot water and the crude petroleum is added and mixed with a spray pump, after which it is diluted with the desired amount of water.

An emulsion of crude petroleum made in this way remains fluid indefinitely without any tendency to a separation of oil and water. Brief directions are also given for the preparation of emulsions and other oils.

**The fumigation of dwelling houses for vermin**, C. FULLER (*Natal Agr. Jour. and Min. Rec.*, 8 (1905), No. 5, pp. 467-464, fig. 1).—Directions are given for the use of hydrocyanic-acid gas in destroying bedbugs, cockroaches, and other insects in houses. For large rooms several generators may be arranged, and care should be exercised to prevent one of them from being set in operation before the others if the attendant is still in the room. It is recommended that the period of fumigation be 6 to 8 hours if possible, but never less than 3 hours.

**Key to the known larvæ of the mosquitoes of the United States**, H. G. DYAR (*U. S. Dept. Agr., Bur. Ent. Circ.* 72, pp. 6, fig. 1).—This circular contains an analytical key intended for use in the identification of the known larvæ of mosquitoes.

**House flies**, L. O. HOWARD (*U. S. Dept. Agr., Bur. Ent. Circ.* 71, pp. 9, figs. 9).—This is a revision of Circular 35 (*E. S. R.*, 10, p. 654).

**The distribution of tsetse flies in French East Africa and in Kongo**, A. LAVERAN (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 23, pp. 929-932).—Brief

notes are given on the distribution of various species of *Glossina* and *Tabanus* in Senegal, French Kongo, New Anvers, the district of Ubangi, and other neighboring countries.

**The horse botfly** (*Jour. Bd. Agr. [London]*, 12 (1905), No. 2, pp. 108-110, figs. 2).—The botfly is quite common in the central and southern part of England, but almost entirely absent from the northern part of the country. The common species observed in England is *Gastrophilus equi*, but it is considered desirable that the point should be determined whether other species also occur.

**Observations on the bionomics of *Auchmeromyia leuteola***, F. C. WELLMAN (*Ent. News*, 17 (1906), No. 2, pp. 64-67, figs. 3).—The larvæ of this fly is a blood-sucking maggot which has previously been referred to from South Africa. The author followed the complete life history of the species and gives notes on its method of attacking man.

**Anatomy of *Boophilus annulatus***, S. R. WILLIAMS (*Proc. Boston Soc. Nat. Hist.*, 32, No. 8, pp. 313-334, pls. 5, figs. 3).—The external anatomy, habits, and life history of the cattle tick have been quite thoroughly worked out. The present article, however, is apparently the first attempt to describe in detail the various features of the internal anatomy of the cattle tick.

It appears that the internal anatomy of this pest differs decidedly from that of *Ixodes ricinus* described in 1861 by Pagenstecher. In order to study the internal anatomy of cattle ticks it was found necessary to allow the body to shrink somewhat in alcohol. This makes it possible to remove the chitin which otherwise interferes with making sections. According to the author, the external porous areas on cattle ticks are sense organs. The alimentary canal is a slightly curved tube provided with 6 large diverticula, which occupy most of the body of the tick. The adult females appear to eject nothing from the alimentary canal or the renal organs.

**Apiculture**, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, 13 (1905), pp. 403-405, pls. 4).—On account of the growing importance of the bee industry in New Zealand, it is recommended that an efficient expert be appointed for the purpose of giving instruction to bee raisers. The author has inspected about 2,500 colonies of bees, and brief notes are presented on foul brood, bee moth, and other troubles which affect the bee raiser.

**Beekeeping: How to meet its dangers and difficulties**, B. N. GATES (*Agr. of Mass.*, 52 (1904), pp. 411-426).—Statistics are given on the amount of honey produced in Massachusetts and certain other States with which Massachusetts is compared. In wintering bees it is essential that the colonies have plenty of stores and be given a uniform temperature, without too much moisture. Particular attention is given to the discussion of the bee moth, robbing, foul brood, and other diseases of bees.

**Scientific queen raising**, A. H. W. CLARKSON (*Queensland Agr. Jour.*, 16 (1905), No. 1, pp. 118-122).—The author argues that it is useless to attempt to rear queens in weak colonies. The nuclei should be strong, since otherwise the necessary amount of food and the proper temperature can not be secured for the development of queens. As a standard for good queens it is considered that they should be able to lay from 2,000 to 3,000 eggs per day during the proper season of the year.

The method recommended by the author consists in transferring a frame of queen cells with royal jelly to a strong colony of bees which, at the time, is working vigorously in the upper part of the hive. Before this is done a couple of frames containing young larvæ could be removed from the lower to the upper story and a queen placed between the bottom and top story. As soon as the bees find that the brood is not increasing in the top story they proceed to raise a new queen.

**Ventilation of bees**, DEVAUCHELLE (*Apiculteur*, 50 (1906), No. 1, pp. 10-14).—The author presents a discussion of the phenomenon of bees ventilating the hive by wing movements at the entrance to the hive. It is believed that the purpose of this is to lower the temperature in the hive and renew the air in order to increase the evaporation of nectar.

**Bees and the color of flowers**, G. BONNIER (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 24, pp. 988-994).—After carrying on numerous observations with regard to the attraction of the color of flowers for bees, the author comes to the conclusion that the color of flowers does not exercise any apparent influence upon the worker bee.

**Catalogue of the exhibit of economic entomology at the Lewis and Clark Centennial Exposition, Portland, Oregon, 1905**, R. P. CURRIE (*U. S. Dept. Agr., Bur. Ent. Bul.* 53, pp. 127).—This catalogue was designed to increase the usefulness of the exhibit of the Bureau of Entomology in Portland by furnishing information regarding the insects contained in that exhibit. The species represented were largely the same as those shown at the St. Louis Fair, but some insects of interest only to eastern localities were omitted.

### FOODS—HUMAN NUTRITION.

**Standards of purity for food products** (*U. S. Dept. Agr., Office Sec. Circ.* 17, pp. 7).—The food materials for which standards are proposed include dried, evaporated, canned, and preserved fruits and similar products, flavoring extracts, oils used in the preparation of extracts, olive oil, cotton-seed oil, and other edible vegetable oils, and table salt.

A flavoring extract is defined as "a solution in ethyl alcohol of proper strength of the sapid and odorous principles derived from an aromatic plant, or parts of the plant, with or without its coloring matter, and conforms in name to the plant used in its preparation."

The various flavoring extracts described are intended solely for food purposes and, it is pointed out, are not to be confounded with similar preparations described in the *Pharmacopœia* for medicinal purposes.

This publication supplements a circular previously noted (*E. S. R.*, 16, p. 894).

**Legislation regulating the sale of foods** (*Rev. Soc. Sci. Hyg. Aliment.*, 2 (1905), No. 6, pp. 467-640).—A summary of laws regarding the regulation of foods, previously noted, is continued (*E. S. R.*, 17, p. 59). The present installment includes Holland, Spain, Portugal, Sweden, Denmark, France, and the United States.

**The microscopy of vegetable foods**, A. L. WINTON (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd.*, 1906, pp. XVI + 701, figs. 589).—This volume, which was prepared with the collaboration of J. Moeller, summarizes the results of a large number of original investigations on the histology of products of vegetable origin, and is designed for the use of food analysts, agricultural chemists, pharmacists, and others engaged in the examination of foods, as well as the physician who may be called upon to identify vegetable substances in stomach contents and feces.

It has been the author's aim to make the volume comprehensive and to have it cover the important vegetable foods used by man and domestic animals, and to present the material in such form that it will be available for ready reference. In preparing the work the author states that leading authorities have been consulted and "credit has frequently been given for important discoveries, although so far as possible the writer has based his descriptions on his own observations." Laboratory equipment, methods, and general principles relating to the microscopical examination of vegetable food products are discussed.

The materials described and illustrated include grain and its products and impurities, oil seeds and oil cakes, legumes, nuts, fruit and fruit products, vegetables, alkaloidal products and their substitutes, spices and condiments, and commercial starches. The illustrations, very many of them from original drawings, are a special feature of the volume and add much to its value. A bibliography, glossary, and index are included. The volume as a whole is an important contribution to the subject of vegetable histology, which, both as a pure and applied science, has hitherto been taken up almost exclusively by European investigators.

**Food products**, A. L. WINTON ET AL. (*Connecticut State Sta. Rpt. 1905, pt. 2, pp. 107-144*).—Under the provisions of the State pure-food law 1,347 samples of milk, olive oil and substitutes, coffee, spices, chocolate, candies, jams, extracts, and similar products were examined, over half of the samples being collected by the station and the remainder submitted by the dairy commissioners and by health officers, consumers, and dealers. Of these samples 388 were adulterated or below the standard, 94 were compounds, while the remaining 865 were not found to be adulterated.

**Cereal breakfast foods**, C. D. WOODS and H. SNYDER (*U. S. Dept. Agr., Farmers' Bul. 249, pp. 36*).—The results of investigations carried on at a number of experiment stations on the digestibility and nutritive value of cereal breakfast foods are summarized, as well as general information on this important class of food products. Some of the questions discussed are the preparation of modern cereal breakfast foods, predigested and malted goods, cooking, the absorption of water by different cereals and their solubility, cost of cereal breakfast foods as compared with other foods, and the place of these foods in the diet. Information regarding the use of cereal products as coffee substitutes is also summarized.

"In the selection of cereal breakfast foods the consumer may be guided by the results of analyses of disinterested chemists, by the digestibility as determined by actual tests, by cost, by taste, by economy, or by the observed effects of the goods upon individuals. It seems fair to conclude that the chemical composition, considered in connection with digestibility and cost, furnishes a satisfactory guide for selection, due attention being paid to palatability and individual preferences.

"All things considered the cereal breakfast foods as a class are nutritious, convenient, and reasonably economical foods and worthy of an important place in the diet when judiciously combined with other foods."

**Food and the principles of dietetics**, R. HUTCHISON (*London: Edward Arnold, 1906, pp. 582; rev. in Brit. Med. Jour., 1906, No. 2362, p. 806*).—This handbook has been revised and some new material added, including among other topics a discussion of underfeeding.

**Unpolished rice**, H. S. CLUBB (*Philadelphia: Vegetarian Society of America, 1905, pp. 32*).—On account of its higher protein content the use of unpolished instead of polished rice is advocated. In addition to discussing the various topics connected with the use of rice in the diet the author has summarized a large number of recipes for preparing it for the table.

**The digestibility of flour made from legumes**, M. WINTGEN (*Veroffentl. Mil. Sanitätsw., 1905, No. 29, pp. 37-55; abs. in Ztschr. Untersuch. Nahr. u. Genussm., 11 (1906), No. 4, pp. 225, 226*).—Artificial and natural digestion experiments with pea meal, bean meal, and lentil meal are reported. As shown by the experiments with man the pea meal was more digestible than the other sorts studied.

**Preserved eggs and egg substitutes**, A. BEYTHIEN and L. WATERS (*Ztschr. Untersuch. Nahr. u. Genussm., 11 (1906), No. 5, pp. 272-274*).—Data are reported regarding the composition of egg powders and similar goods.

**Chemical change produced in foods, etc.** (*Pure Products, 2 (1906), Nos. 2, pp. 70-72; 3, pp. 118-120*).—A summary of data regarding the chemical changes due to micro-organisms, etc., which take place when food of different sorts is stored or preserved in different ways.

**Preserved fruits in lacquered tins** (*Lancet [London], 1906, I, No. 8, pp. 529, 530*).—Examination of fruits in tin cans with the interior surface lacquered showed that this method of treating the can prevented metallic contamination.

A number of experiments were made with this method of canning, using raspberries, strawberries, gooseberries, plums, blackberries, greengages, and damsons. "In no instance was there the least indication of any action on the tin and not a trace of tin could be found in the sirup, while the color of the fruit was satisfactorily preserved."

**Pure British dried vegetables** (*Lancet* [London], 1906, I, No. 11, p. 766).—Commercial dried or evaporated vegetables are described, which are regarded as of good quality. It is stated that the condition of the food constituents was not changed by evaporation, the albumins of the dried product being still soluble. Color and freshness of flavor, it is stated, were also little affected.

**The occurrence of esters in bananas**, F. ROTHENBACH and L. EBERLEIN (*Deut. Essigindus.*, 1905, No. 9, pp. 81, 82; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 4, pp. 230, 231).—The authors report isovaleric-isoamyl ester and ethyl ester in bananas. The possible occurrence of amyl acetate is also noted. Experiments showed that ester formation did not depend upon micro-organisms, but was a product of cell activity.

**Commercial extract of lemon**, A. MCGILL (*Lab. Inland Rev. Dept. [Canada], Bul. 114, pp. 15*).—Considerable range in alcohol strength and in lemon oil content was noted. Of the 110 samples examined, 2 contained 6 per cent or more of lemon oil and 78 less than 1 per cent. No methyl alcohol was found.

**Coffees without caffein**, G. BERTRAND (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 3, pp. 209-211).—According to the author's analyses, the berries of *Coffea gallienii*, *C. bonnierii*, *C. mogenetii*, and *C. humblotiana* contain no caffein. The ash, water, and total nitrogen in the samples were also determined. A sample of *C. mauritiana* contained only a very small percentage of caffein, namely, 0.7 gm. per kilogram. A sample of *C. arabica*, analyzed at the same time, showed 13.4 gm. caffein per kilogram.

**Maple sugar and sirup**, W. F. HUBBARD (*U. S. Dept. Agr., Farmers' Bul. 252, pp. 36, figs. 9*).—This bulletin is based on a publication of the Bureau of Forestry previously noted (*E. S. R.*, 17, pp. 774, 790).

**Physiological studies of vegetarian diet**, W. CASPARI (*Arch. Physiol. [Pfluger]*, 109 (1905), No. 11-12, pp. 473-595, pls. 3).—Extended studies are reported of vegetarian and raw fruitarian diet. In connection with this work studies were made of the metabolism of nitrogen, the digestibility of the diet, and the effect of the food on the respiratory quotient. Two of the subjects were professional athletes, one a vegetarian, the other not. The general conclusions drawn were in effect as follows:

~A strictly vegetable diet, even when made up of raw foods, is able to nourish the body in youth and maintain it at the highest degree of physical strength and mental and physical power, yet this sort of diet is considered unsatisfactory because the nutrients, particularly protein, are not well assimilated because the food is lacking in flavor and is of large volume. The vegetarian diet when made up of ordinary vegetables, fruits, etc., has an advantage in that it is not expensive.

It did not appear that the vegetarian diet surpassed the ordinary diet on account of the small amount of uric acid formed. As is commonly claimed the amount of purin bodies formed was small as compared with the quantity obtained with an excessive meat diet and under certain pathological conditions. As regards the performance of muscular work the vegetarian diet certainly is not superior to the ordinary mixed diet.

**A respiration calorimeter with appliances for the direct determination of oxygen**, W. O. ATWATER and F. G. BENEDICT (*Washington, D. C.: Carnegie Institution of Washington, 1905, pp. X+193, figs. 49*).—This volume includes a detailed description of a respiration calorimeter and accessory apparatus which the authors have devised for experiments with man, together with the results of check experiments to determine the accuracy of the apparatus and an experiment with man.

The respiration calorimeter has been in process of development for 12 years, and much of the work connected with it has been a part of the cooperative nutrition investigations of the Department of Agriculture and reported in Department publications (*E. S. R.*, 15, p. 698, 17, p. 165). Under the auspices of the Carnegie Institu-

tion very important changes in the apparatus have been introduced and the method of experimenting has been modified to include the direct determination of oxygen. A quantity of air circulates through the apparatus and the carbon dioxide and water eliminated in the respiratory products are removed by passing the air current through soda-lime mixture and through sulphuric acid. As the air current passes back into the respiration chamber oxygen is added to make up for that used by the subject, the amount being determined by weighing the cylinder containing the oxygen before and after the addition is made.

The calorimeter may be fairly designated an instrument of precision and serves for the very accurate measurement of energy, carbon dioxide, water, and oxygen in experiments with man extending over a number of days, under various conditions of work and rest.

In connection with the experiments, the balance of income and outgo of nitrogen and other food constituents is taken into account so that the experiments furnish data for considering the total income and outgo of matter and energy in addition to the respiratory quotient.

"In experiments with man as carried out with this apparatus and accessories, the following determinations of intake and output of material are made:

"The intake [as regards matter] consists of food, drink, and oxygen from respired air. The amounts are determined by weighing. The analyses include determinations of water, ash, nitrogen, carbon, hydrogen (organic), and at times sulphur and phosphorus. The output of material consists of products of respiration and perspiration, urine, and feces. The dry matter of feces and urine is subjected to a series of analyses similar to those for food, and the water and carbon dioxide of perspiration and respiration are determined according to the methods discussed in this report. The determinations of nitrogen in perspiration are made, when necessary. . . .

"[In the case of energy] the intake is derived from the potential energy, i. e., heats of combustion of the food. The output consists of sensible heat given off from the body, the latent heat of the water vaporized, and the potential energy, i. e., heat of combustion of the unoxidized portions of the dry matter of urine and feces. In certain cases, e. g., work experiments, a not inconsiderable portion of the output is in the heat equivalent of external muscular work. . . .

"The heats of oxidation are determined by burning the substances in the bomb calorimeter; the heat given off from the body is measured by the respiration calorimeter; the external work is measured by a specially devised ergometer. Allowance is made for heat introduced and removed by the ventilating air current, food, feces, and urine, and for that involved in changes of body temperature, which is also measured. . . .

"Since the completion of the new apparatus, 22 experiments with 5 different subjects, covering a total of 60 days, have been conducted. These experiments lasted from 1 to 13 days, during which time the subject remained inclosed in the calorimeter chamber. Ordinarily the experiment lasts 3 or 4 days. In general, each experiment is preceded by a preliminary period outside the chamber, during which the subject is given the special diet to be tested, and his habits of life so modified as to conform with those to be followed in the chamber. When the subject is to be engaged in muscular work, he devotes considerable time in the preliminary days to riding a bicycle in the open air, the amount of work performed being as nearly as can be judged equivalent to that to be done later on the bicycle ergometer inside the chamber.

"The food for the whole experimental period, including the preliminary days, is carefully weighed, sampled, and daily portions placed in proper containers ready for consumption. The more easily decomposed materials, such as milk and cream, are sampled, weighed, and analyzed each day. The bread and meat when used are

carefully sterilized in glass jars. The diet may be so planned as to maintain a uniform quantity of nitrogen and a constant calorific value from day to day."

**Respiratory quotient in static work, II**, A. BORNSTEIN and A. OTT (*Arch. Physiol. [Pfluger]*, 109 (1905), No. 11-12, pp. 621-627).—On an average of 17 experiments it was found that the work required in standing was equivalent to 156 calories per minute. Data are also given regarding the expenditure of energy when a pack was carried on the back.

**Respiratory quotient in static work, III**, A. BORNSTEIN and B. VON GARTZEN (*Arch. Physiol. [Pfluger]*, 109 (1905), No. 11-12, pp. 628-633).—The data reported have to do with the effect of weighting the chest on the oxygen consumed and the carbon dioxide excreted.

**Alcohol, sugar, and caffeine, and their effect upon muscular work, I**, IOTYKO (*Rev. Soc. Sci. Hyg. Aliment.*, 2 (1905), No. 5, pp. 483-491, fig. 1).—From experiments in which muscular work was measured with an ergograph, the conclusion was reached that sugar is an excellent food, a direct source of energy in the muscles, and not an excitant. Caffeine is considered as an excitant of the nervous system and, in the author's opinion, is of great importance as a tonic, though it has probably no nutritive value.

**The after effect of muscular work upon water vapor secretion**, H. WOLPERT and F. PETERS (*Arch. Hyg.*, 55 (1906), No. 3, pp. 309-322).—The increased excretion of water vapor due to muscular work can be noted for several hours after the work has ceased.

**The daily curve of water vapor excretion in man**, H. WOLPERT and F. PETERS (*Arch. Hyg.*, 55 (1906), No. 3, pp. 299-308, *dgm.* 1).—From their investigations the authors conclude that neither the time of day nor the diet is a direct cause of variation in the amount of water vapor excreted. The average amount excreted per day was 1,650 gm. at, in still air, a temperature of 24° C and containing 65 per cent moisture.

**Observations on creatin excretion in man**, C. J. C. VAN HOOGENHUYZE and H. VERPLOGH (*Ztschr. Physiol. Chem.*, 46 (1905), No. 5-6, pp. 415-471, *figs.* 8).—In the experiments reported muscular work did not exercise any marked effect on the excretion of creatin except in the case of a fasting subject, when an increase was noticeable. Gelatin and casein added to the ration did not increase creatin excretion, and the addition of 5 eggs caused only a slight increase. Other questions relating to creatin formation and excretion were also studied and the investigation as a whole is discussed with reference to Folin's theory of nitrogen metabolism.

**Report of the departmental committee on vagrancy**, J. L. WHARTON ET AL. (*London: Wyman & Sons, Ltd.*, 1906, pp. VI + 123).—The housing, care, and management of vagrants, and their relation toward other classes are considered, one of the questions taken up being the dietary for casual wards and labor colonies. The dietary recommended for casual wards would cost about 39 cts. per head per week and would furnish 63 gm. protein and 2,500 calories per head per day, and that recommended for labor colonies would cost about 33 cts. per head per week and furnish 66 gm. protein and 2,236 calories per head per day.

## ANIMAL PRODUCTION.

**Commercial feeding stuffs**, E. H. JENKINS and A. L. WINTON (*Connecticut State Sta. Rpt.* 1905, pt. 3, pp. 145-188).—The feeding stuffs examined under the State law included cotton-seed meal, linseed meal, rape-seed meal, wheat bran, wheat middlings, wheat mixed feed, maize meal, gluten meal and feed, hominy feed, rye feed, malt sprouts, dried distillery grains, buckwheat middlings, alfalfa meal, miscellaneous mixed feeds, proprietary horse feeds, proprietary and other dairy and stock feeds, proprietary poultry feeds, beef scrap, and meat meal.

"The examinations of these feeds show that in many cases the dealers do not give the guaranties, as required by law. When given, they are too often misleading, being much higher than the composition of the goods warrants. This is especially noticeable in the gluten meals and gluten feeds.

"The mixtures of wheat feed and corncobs, formerly sold, illegally, as 'wheat feed,' are now sold under distinctive names and with a guaranty; thus complying with the law.

"There are still on the market a large number of low-grade mixed feeds, of very moderate feeding value, but sold for only a few dollars per ton less than the standard high-grade feeds."

In most cases a feeder can not use to advantage any boughten feed containing less than 15 per cent of protein.

"Ready-mixed feeds, made of a number of by-products or factory wastes, may wisely be let alone, unless the buyer can see for himself out of just what raw material the mixture is being prepared. Low grade, damaged corn, shriveled wheat, peanut refuse and wheat screenings containing many weed seeds, are not infrequently found in such feeds by careful examination, but are not easy for the buyer himself to recognize."

**Commercial feeding stuffs sold in Maryland, H. B. McDONNELL ET AL. (*Md. Agr. (vol. Quart., 1905, No. 30, pp. 7)*).**—The protein and fat were determined under the State feeding-stuff law in a number of samples of meat meal and other poultry feeds of animal origin, cotton-seed meal, linseed meal, unpressed flaxseed meal, gluten feed, molasses grains, wheat middlings, alfalfa meal, short-cut alfalfa, dried distillers' grains, wheat bran, wheat middlings, proprietary poultry feeds, pigeon feed, ground oats, sugar-beet pulp feeds, corn bran, and mixed and proprietary feeds. "We have reason to believe that ground peanut hulls are being used to some extent to adulterate feeds, probably bran, and purchasers should be on the lookout for this, as the hulls are worthless as a feed."

**Concentrated feeding stuffs, J. P. STREET, W. P. ALLEN, and V. J. CARBERRY (*New Jersey Stat. Bul. 193, pp. 38*).**—The feeding stuffs examined under the State pure-food law included cotton-seed meal, linseed meal (old process), germ meal, gluten feed, corn bran, hominy meal and similar goods, distillers' and brewers' grains, malt sprouts, molasses grains, mixed and proprietary feeds, biscuit refuse, biscuit refuse and milk, alfalfa meal, barley feed, dried sugar beet pulp, meat meal and proprietary poultry feeds, calf meal, wheat bran, wheat middlings, feeding flour, wheat feed, rye bran, rye feed, corn meal, corn-and-cob meal, mixed ground grains, buckwheat middlings, buckwheat bran, and buckwheat feed.

"Of the 125 different brands of feed received, and which should have been guaranteed, four failed to meet this requirement.

"Of the 241 samples which were guaranteed, 90 were deficient, 71 of these being low in protein.

"Of the 103 samples which did not require a guarantee, all were pure products, but the wheat brans and feeding flours were below normal quality.

"No direct adulteration is reported, but there are a number of feeds on the market whose composition does not warrant the high guarantees they carry.

"The purchaser of protein will rarely find any feed containing less than 15 per cent of protein a desirable or an economical purchase, and in all cases a strict regard must be given to the amount of nutrients guaranteed and the prices asked for the same."

**Third report on concentrated feeding stuffs and cotton-seed meal, B. W. KILGORE, C. D. HARRIS, and J. C. PHELPS (*Bul. N. C. Dept. Agr., 26 (1905), No. 11, pp. 63, figs. 7*).**—Under the provisions of the State feeding-stuff law 534 samples of wheat bran, wheat middlings, bran and shorts, ship stuff, oat feeds, corn and oat feeds, rice meal, rice feed, peanut bran, peanut feed, molasses or sugar feeds, malt sprouts, gluten feed, hominy feeds and chops, cotton-seed meal, cotton-seed hulls, cotton-seed feeds, and mixed and proprietary feeds.

About one-third of the samples of wheat bran were found to contain corn bran, rice chaff, and peanut shells. One-third of the samples of bran and shorts were also found to be mixtures. In the case of corn and oat feeds, molasses feeds, hominy feeds, cotton-seed feeds, and mixed and proprietary feeds most of the samples were of good quality. In the case of other classes of goods analyzed a larger proportion of the goods were below the standard. "Good grades of cotton-seed meal contain 43 per cent or more of protein. This means that they have about 7 per cent of nitrogen, which is equal to 8.5 per cent of ammonia. Meals in past years especially have not infrequently been considerably higher than this." Of the 120 samples examined 37 were below the standard, 7.5 per cent ammonia.

**Commercial feeding stuffs**, J. L. HILLS, C. H. JONES, and F. M. HOLLISTER (*Vermont Sta. Bul.* 117, pp. 8).—Some 150 samples of commercial feeding stuffs were collected for examination under the State law in the spring of 1905. These included cotton-seed meal, linseed meal, gluten meals and feeds, distillers' dried grains, oat feeds, corn and oat feeds, hominy feed, sugar feed, ground beef scraps, wheat offals, and provenders.

**Commercial feeding stuffs**, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 118, pp. 9-16).—In the autumn of 1905, 270 samples of commercial feeding stuffs were collected for inspection under the State law, including cotton-seed meal, linseed meal, gluten meals and feeds, distillers' dried grains, oat feeds, corn and oat feeds and similar goods, hominy feeds, mixed feeds, molasses grains, molasses beet pulp, alfalfa meal, calf meal, provenders, and wheat offals. The cotton-seed meals contained 41.5 per cent protein as compared with 44 per cent found in the samples on sale in the State up to a year or two ago. A low protein content has been observed elsewhere and has been attributed to general crop conditions.

**Olive pomace as a feeding stuff**, E. MARCHI (2. *Cong. Internat. Aliment. Ration. Bétail*, 1905, *Raps.*, pp. 163-172).—From a study of the composition of olive pulp and a summary of data regarding its feeding value, the conclusion is reached that this material can be used in the feeding of farm animals, but that it should be mixed with some material which is low in fat and carbohydrates, such as legumes, commercial by-products, skim milk, casein, dried blood, etc.

**Adulteration of feeding stuffs**, C. GORUSSO (2. *Cong. Internat. Aliment. Ration. Bétail*, 1905, *Raps.*, pp. 205-209).—Work connected with feeding-stuff inspection in Italy is spoken of. The author believes that chemical analysis furnishes a satisfactory basis for such work.

**Alfalfa for the growing and fattening of animals in the Great Plains region**, I. D. GRAHAM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 86, pp. 242-267).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R.*, 17, p. 686).

**The effect of the ration on the value of the manure**, J. M. BARTLETT (*Maine Sta. Bul.* 126, pp. 45-48).—In digestion experiments with steers the potash and phosphoric acid in the excretory products were determined, as well as the nitrogen. The rations were made up of hay alone and with spring and winter wheat bran and cotton-seed meal. The following table summarizes the values found:

*The money value of the fertilizing elements excreted on each ration and per 100 lbs. of each feed.*

Ration.	Nitrogen.	Phosphoric acid.	Potash.	Total value.
	Cents.	Cents.	Cents.	Cents.
Hay alone .....	5.36	0.39	2.98	8.63
Hay and spring wheat bran .....	10.40	2.08	8.95	16.88
Hay and winter wheat bran .....	9.52	1.67	8.70	14.89
Hay and cottonseed meal .....	15.30	1.32	9.95	20.57
100 lbs. hay .....	13.50	.98	7.45	21.93
100 lbs. spring wheat bran .....	37.80	11.91	8.98	58.64
100 lbs. winter wheat bran .....	31.90	8.85	7.27	48.02
100 lbs. cottonseed meal .....	99.40	9.30	9.60	118.30

"In the first experiment with hay alone, more nitrogen was found in the excretions than was taken in the food. This discrepancy was probably due to insufficient nitrogen in the ration to maintain the animals and they lost flesh, excreting some body nitrogen. . . .

"The larger part of the nitrogen, the most expensive element, and potash are given off in the urine, hence the importance of saving all of this most valuable part of the manure. Not only are other elements found in large quantities in the liquid, but they are in much more available form than in the solid. Only traces of phosphoric acid were found in the urine."

**The nitrogen balance in the nutrition of ruminants**, A. GOUIN and P. ANDOUARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 122-124*).—Data are reported regarding the proportion of nitrogen excreted in the urine and feces. The authors believe that such data should be used with caution, especially when it is remembered that the food material remains a long time in the digestive tract of Herbivora.

**Concerning the assimilation of protein in the animal body**, E. ABDERHALDEN and F. SAMUELY (*Ztschr. Physiol. Chem., 46 (1905), No. 1-2, pp. 193-200*).—The examination of the blood of horses under different conditions showed that the protein of food was without influence on the composition of serum proteid.

**The nutritive value of amids**, B. VON STRUSIEWICZ (*Ztschr. Biol., 47 (1905), p. 143*).—From experiments with sheep the author concludes that amids have the same value as proteids, a deduction not in accord with the consensus of opinion of other investigators.

**Phosphates in the ration of young animals**, RASQUIN (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 62-68*).—The work of other investigators is summarized and tests briefly reported in which rations with and without added phosphate (ground bone) were studied with chickens. On a powdered bone ration the gain in weight was greater and the skeleton was heavier and contained a larger amount of lime and phosphoric acid. Mineral phosphates, the author concludes, are of value in the feeding of young animals.

**Watering farm animals**, P. WERY (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 86-91*).—Various questions concerned with the wholesomeness of the water supply are taken up. The author recommends that more public watering troughs be provided which will give a constant supply of water of good quality.

**Proceedings of Second International Congress for the Rational Feeding of Farm Animals** (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Compt. Rend., pp. 192*).—The programmes, list of members, proceedings, etc., of the Second International Congress for the Rational Feeding of Farm Animals, which was held in 1905 at the Universal Exposition at Liège.

**Résumé of the principal experiments on cattle feeding which have been carried on in the low countries**, J. J. O. DE VRIES (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 149-162*).—Dutch investigations on cattle feeding are summarized. The author believes that rations which have given satisfactory results in practice should be studied by scientific methods.

**Feeding experiments with cattle designed for fattening and pasture**, L. BAUWENS (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 144-148*).—Belgian studies are summarized comparing horse beans with and without other concentrated feed for young cattle, but conclusions are not drawn.

**Experiments on fattening calves**, F. SMEYERS (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 197-204*).—The tests reported show that feeding whole milk to calves is not profitable.

Data are summarized regarding skim milk supplemented by other feeds, and attention is directed to the bad results which were obtained in the feeding of sour milk. The author believes that the question of the better utilization of skim milk

should be studied and that the degree of acidity which may be permitted without harm should be determined.

**Cost of maintenance and growth of ruminants**, A. GOUIN and P. ANDOUARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 115-121*).—On the basis of experimental evidence, the authors conclude that the energy required for a kilogram of gain in body weight is about 1,200 calories per square meter surface area. Powdered bone is considered an important aid in practical feeding.

**Western feeds for beef production**, J. G. HANEY and O. H. ELLING (*Kansas Sta. Bul. 132, pp. 21-52, figs. 9*).—Using 64 grade Shorthorn and Hereford cattle divided into 8 uniform lots, the value of corn-and-cob meal and Kafir corn meal with alfalfa hay, with Kafir corn hay, and with sorghum hay was studied, as well as ground wheat with alfalfa hay, and a mixed ration containing all the other feeding stuffs enumerated.

The greatest gain in the 152 days of the test, 338 lbs., was noted with the lot fed corn-and-cob meal and alfalfa hay, and the smallest gain, 160 lbs., with the lot fed ground Kafir corn and sorghum hay. Generally speaking, the lots fed the rations containing alfalfa hay and the mixed ration made larger gains than the other lots.

The cost of a pound of gain ranged from 5.13 cts. with the corn-and-cob meal and alfalfa hay ration to 11.74 cts. on ground Kafir corn and sorghum hay.

In the case of the lots fed ground grain and alfalfa hay the dressed weight was on an average 60 per cent of the live weight in round numbers. In the case of the other lots it was somewhat lower. Other data regarding the slaughter test are recorded.

"For beef production, ground Kafir corn is about equal, pound for pound, to corn-and-cob meal when alfalfa hay is fed with either of these concentrates. . . . Ground wheat and alfalfa hay, fed together, is not an economical ration for beef on account of the loosening effect of these feeds on the steers and the expensiveness of the wheat. . . .

"A matter of this experiment of considerable interest, especially to the western farmer, is the part that the various roughages play in beef production. . . . One bushel of corn-and-cob meal fed with alfalfa hay as roughage produced 11.8 lbs. of flesh, while the same amount of corn-and-cob meal fed with sorghum hay as a roughage gave in return only 6.25 lbs. of flesh; thus, a difference of 5.5 lbs., or 88 per cent in favor of the alfalfa hay ration. . . .

"It is the opinion of the writer that the western feeds grown without irrigation have the chief food constituents in a slightly different proportion from those grown under more favorable conditions, though the nutritive ratio of the rations fed and the profit per steer have a direct relation to each other. For practical work the results would be little changed by this difference in composition."

**Highland cattle**, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus Circ. 88, pp. 227-241*).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R.*, 17, p. 689).

**Pigs and bacon** (*Jour. Jamaica Agr. Soc., 10 (1906), No. 3, pp. 108-110*).—Data are summarized showing that bacon curing may be profitably carried on in Jamaica with local-grown pigs. The majority of the local feeding stuffs, it is pointed out, are very rich in carbohydrates and tend to produce fat rather than flesh. The pulp remaining after cotton-seed oil is expressed, peas, and cowpeas are spoken of as very satisfactory feeds for pigs raised for bacon.

**Feeding of horses**, E. LAVALARD (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 13-27*).—A summary and discussion of recent horse-feeding experiments in France, particularly those carried on upon a large scale.

**Influence of foods containing sugar upon the digestibility of rations of horses**, J. ALQUIER (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Raps., pp. 1-12*).—On the basis of experimental evidence it is stated that sugar did not appreciably affect the digestibility of the nutrients of a ration even when as much as 5 or 6 kg.

per 1,000 kg. body weight was consumed. Sirup and molasses in smaller quantities, however, decreased digestibility, a fact which is explained by the laxative properties of the alkaline salts in beet molasses.

**The toxicity and hygienic and therapeutic rôle of the mineral matter of molasses for horses,** J. ALQUIER (*2. Cong. Internat. Aliment. Ration. Bétail, 1905, Rups., pp. 69-85*).—From the experimental evidence presented the conclusion was drawn that molasses is harmless and a hygienic nutritive material when the amount consumed per day does not exceed 3 or 4 kg. per horse.

**Hunter-horse production in Ireland,** W. J. KENNEDY (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 87, pp. 187-225, pls. 8*).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R., 17, p. 691*).

**The poultry industry of Petaluma, California,** P. H. LAWLER (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 92, pp. 316-322, pls. 3*).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R., 17, p. 692*).

## DAIRY FARMING—DAIRYING—AGROTECHNY.

**The influence of changes in feeding upon milk production,** J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 341-376*).—This is a compilation and discussion of the data obtained in the feeding trials reported in the tenth to the sixteenth annual reports of the station (1896-1903), inclusive, and relates to the effect upon production of changes in the total and digestible dry matter, digestible protein, digestible carbohydrates, and calories. Many deductions are made from the numerous tables which show in a condensed form, food consumption; production of milk, total solids, and fat with the food cost of each; and production proportioned to food consumption.

Among the author's generalizations are the following:

"(1) The testimony afforded by the results as between different rations and the same ration fed in different amounts is so nearly alike, speaking broadly, that one may safely group them together and argue on the basis of variations in dry matter or in nutrient consumption regardless of their origin.

"(2) When like quantities of the several nutrients were eaten, production was unaltered.

"(3) A 6 per cent increase or decrease in total dry matter eaten was accompanied by a corresponding 2 per cent change in yield; a 10 per cent increase or decrease, by a 5 per cent change in yield. . . .

"(4) A 7 per cent increase or decrease in digestible dry matter eaten was accompanied by a 3 per cent change in yield; a 12 per cent increase or decrease, by a 6 per cent change in yield; or, in other words, as food varied so did the yield, but to a less degree. . . .

"(5) As for digestible dry matter, so for digestible carbohydrates and for calories, word for word and, essentially, figure for figure.

"(6) A 3 per cent increase or decrease in digestible protein eaten had no effect on production; a 7 per cent increase or decrease was accompanied by a 2 to 3 per cent change in yield; and a 22 per cent increase or decrease by a 4 to 5 per cent change. . . .

"(7) A change in feeding of from more than to less than 15.5 lbs. of digestible nutrients or vice versa caused more decided changes in yield than did modifications in feeding on either side of that line, the average figures being 7 per cent and 4 per cent.

"(8) The nutritive ratio changes were evidenced in production fluctuations much as were those of digestible protein; when it narrowed, production generally increased, and vice versa.

"(9) The ultimate effect of a given food supply upon the milk flow is doubtless the more or less composite result of several coincidently active factors, including, primarily changes in the amounts of digestible nutrients taken as a whole; secondarily, changes in the amounts of digestible protein, and, probably, modifications in the proportions of digestible nutrients consumed in concentrates and in roughage.

"The writer's study of these data leads him to the conclusion that as a whole they do not support the doctrine which lays extreme stress on the paramountcy of protein; that they indicate that a ration with a nutritive ratio wider than 1:6, perhaps as wide as 1.7, or, indeed, in some cases one slightly wider, may prove economically as effective as the traditional 1:5.4; that a sufficiency of nutrients, affording enough available energy for bodily needs, if carrying a fair amount of digestible protein, not necessarily as much as 2.5 pounds, may prove economically as serviceable as does a richer ration."

**Feeding trials with cows**, J. L. HILLS (*Vermont Sta. Rpt. 1905*, pp. 377-404, 428-462).—In the feeding experiments conducted during the year on the same general plan as in previous years (E. S. R., 17, p. 284) tests were made of India wheat meal, hominy feed, cotton-seed meal, and linseed meal, and further data were secured on the extent of experimental error in feeding trials. The experiments included 42 cows and covered a period of 25 weeks.

"India wheat meal, used in medium to small amounts, seemed a fair substitute, pound for pound, for wheat bran, and nearly so for a mixture of equal parts of cotton-seed and linseed meals, an outcome which its analysis would not have led one to expect and which has been confirmed by the concordant results of two seasons' trials.

"Hominy feed proved superior as a milk maker to a rather inferior grade of wheat bran, but did not appear to be the equal of cotton-seed and linseed meals, nor was it as economical a concentrate to use. This outcome has, likewise, the coincident testimony of two years' trials to back it.

"Cotton-seed meal, as compared with linseed meal, seemed to possess a small though measurable advantage as a milk and butter making by-product; and since it cost less and carried a greater plant-food content, it proved economically preferable."

When 6 to 8 animals are fed by the alternation system, it is believed that the experimental error may be held to be a negligible quantity.

**A comparison of feeding trial methods**, J. L. HILLS (*Vermont Sta. Rpt. 1905*, pp. 405-412).—The results obtained during the year agreed with those previously reported, showing, in the opinion of the author, that the simple alternation system of conducting feeding trials is preferable to the combined method, but that the testimony of both is better than that of either alone.

**Influence of sesame feeding on the yield of milk and the quality of milk, butter, and cheese**, MOSER, PETER, and KAPPELI (*Jahresber. Molk. Schule Rütli-Zollikofen*, 18 (1904-5), *Beilage*; *abs. in Milchw. Zentbl.*, 2 (1906), No. 5, pp. 229-232).—Sesame meal to the extent of 1 kg. per head daily produced a satisfactory increase in the yield of milk, but when increased to 1½ kg. was relatively less satisfactory.

The fat content of the milk showed no marked variations due to the feeding. The cheese was apparently unfavorably influenced by the larger quantities of sesame meal fed. The butter was regularly of good quality, although the opinions of the experts were not unanimous as regards the influence of this material on the quality of butter. In any case the influence on the butter was very small. With reference, therefore, to cheese making it is recommended that the quantity of sesame meal be limited to 1 kg. per head daily.

**Influence on the fat content of milk of palm-nut cake as compared with rape-seed cake and peanut cake**, T. VON SZANKOWSKI (*Inaug. Diss., Univ. Halle, 1905*; *abs. in Milchw. Zentbl.*, 2 (1906), No. 5, p. 232).—The author concludes that the palm-nut cake rich in fat exerts a favorable influence on the fat content of milk, the

cake poor in fat exerting more influence on the quantity of milk. The addition of oil acts unfavorably on both the yield and the fat content of the milk which, however, is not the case when the oil is present in the material in a natural state. Rape-seed cake in comparison with palm-nut cake increased the yield of milk but had no influence on the fat content. Peanut cake increased the yield of milk and fat only at the beginning of the feeding period.

**Suggestions for construction of a modern dairy barn** (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 90, pp. 6, figs. 2*).—It is the aim of this circular to present a plan for a dairy barn embodying the best ideas in scientific and sanitary construction consistent with practicability and cheapness.

**Dairying at Park Royal, 1905**, E. MATHEWS (*Jour. Roy. Agr. Soc. England, 66 (1905), pp. 93-111*).—Tests of the butter and milk production of a number of cows of different breeds exhibited at the show of the Royal Agricultural Society in 1905 and several butter-making experiments are reported. The experimental work was largely for the purpose of furnishing object lessons and consisted in making butter from milk obtained after short and long periods of secretion, comparing butter made from the milk of different breeds, churning at different temperatures, etc.

**Record of the station herd for 1904-5**, J. L. HILLS (*Vermont Sta. Rpt. 1905, pp. 42-47*).—Records of 52 cows for the year are reported. Some of the average results are as follows: Yield of milk 5,343 lbs., fat content 5.25 per cent, total solids 14.73 per cent, yield of butter 323.6 lbs., cost of food \$58.31, and proceeds from sale of butter \$96.93.

**On the variations in the constituents of cows' milk during the course of lactation**, F. PRACHFELD (*Inaug. Diss., Univ. Leipzig, 1905; abs. in Milchw. Zentbl., 2 (1906), No. 5, pp. 228, 229*).—The greatest variations in individual constituents occurred during the second and third months and at the close of the lactation period. Variations in fat, sugar, proteids, and ash decreased in the order mentioned. In general, the percentages of fat, proteids, and ash in the milk increased and the percentage of sugar decreased from the beginning to the second or third month of the lactation period, from which time on until the end of the period these relations were reversed.

**Investigations on the relations of the properties of the blood (erythrocytes and hemoglobin) to the productive capacity of milch cows**, F. SCHULTZ (*Fühling's Landw. Ztg., 55 (1906), No. 8, pp. 272-286*).—The investigations, which were made with 3 dairy herds, consisted in counting the red blood corpuscles and estimating the hemoglobin.

The red blood counts were found to be influenced by the age of the cows, stage of pregnancy, variations in altitude, and other causes. Averaging the data for the cows 4 to 6 years of age and of moderate productive capacity, a blood count of 6,320,000 erythrocytes per cubic millimeter was obtained for one herd, the production of which was 2,400 kg. of milk containing 3.76 per cent of fat; 6,640,000 for another herd producing 3,400 kg. of milk containing 3.08 per cent of fat; and 6,960,000 for a third herd producing 4,000 kg. of milk containing 4.01 per cent of fat, indicating a relation between the yield of milk and fat and the number of red blood cells.

The number of red blood cells showed a tendency to increase until the animals reached the age of 4 to 6 years, after which there was a decrease. There was also a decrease in the later stages of pregnancy. More dependence was placed upon the blood counts than upon the hemoglobin estimations, but in general the two determinations varied proportionately. With animals in advanced pregnancy and those kept at high altitudes the hemoglobin was relatively increased, while with young animals and those very productive the proportion of hemoglobin to red cells was reduced. A high content of hemoglobin and a high blood count are considered favorable to milk secretion, and it is suggested that these might be increased by breeding.

**On the lecithin content of milk,** W. KOCH (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 327-330).—What has heretofore been reported as lecithin, the author considers a mixture of lecithin and cephalin. The two substances may be separated by precipitation of the cephalin from an alcoholic solution by means of an ammoniacal solution of lead acetate. Both lecithin and cephalin are considered present in milk in sufficient quantities for estimation. Failure to find lecithin in milk is believed to be due to the common error of treating lecithin as a fat and extracting with ether. Lecithin, however, does not behave the same as a fat and in separating milk it remains for the most part in the skim milk rather than being removed in the cream.

**A comparison of the composition of the casein of human, cows', and goats' milk,** E. ABDERHALDEN and A. SCHITTENHELM (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 458-465).—From 200 gm. of water-free casein prepared from goats' milk, the authors obtained by hydrolysis, alanin 3 gm., leucin 14.8 gm., prolin 9.24 gm., phenylalanin 5.5 gm., glutaminic acid 22.5 gm., aspartic acid 2.2 gm., and tyrosin 9.9 gm. From 7 gm. of casein prepared from human milk 0.33 gm. of tyrosin and 0.28 gm. of glutaminic acid were obtained in the same manner. The albumin from human milk yielded 1.26 per cent of tyrosin and 0.98 per cent of glutaminic acid, the latter being considered much too low.

**Preliminary communication on the glycocoll content of milk proteids,** E. ABDERHALDEN and A. HUNTER (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 404-406).—From a mixture of albumin and globulin prepared from cows' milk there were obtained by hydrolysis with hydrochloric acid, glycocoll, alanin, leucin, prolin, phenylalanin, glutaminic acid, and aspartic acid. Whether the glycocoll comes from the albumin or globulin or both is yet to be determined. The quantity is small, only 1.2 gm. of the ester being obtained from 100 gm. of the albumin or globulin.

**A comparison of udder conformation and of milk production,** J. L. HILLS (*Vermont Sta. Rpt. 1905*, pp. 419-421).—Five cows classed as having well-balanced udders produced on an average 5,725 lbs. of milk and 342 lbs. of butter yearly for an average of 3 years; 18 cows having fairly well-balanced udders, 5,377 lbs. of milk and 333 lbs. of butter yearly for 3.5 years; and 11 cows having poorly formed udders, 5,219 lbs. of milk and 324 lbs. of butter yearly for 3.6 years.

A comparison of the yield of the fore and hind quarters was made with 5 cows, the results showing a yield of 46 per cent for the fore quarters and 54 per cent for the hind quarters, the quality being practically identical. The results were the same whether the fore quarters or the hind quarters were milked first.

**A trial of the Hegelund or Danish method of milking,** J. L. HILLS (*Vermont Sta. Rpt. 1905*, pp. 412-418).—The Hegelund manipulation method was compared with extra-thorough stripping. The tests were made with 7 cows and covered 3 or 4 periods of 5 weeks' duration each.

When the Hegelund method was employed the first portion of the milking obtained in the ordinary manner was reduced in quantity and slightly in quality, but when taken with the residual milk obtained by manipulation the two portions together showed an increase in yield and a slight tendency toward better quality. With extra stripping the first portion showed likewise a reduction in quantity and quality, but when the strippings were added there was a gain in yield in but a single instance.

More food was consumed by the cows when the two special methods were employed, obviously introducing, according to the author, an element of doubt as to how much of the gain was due to manipulation and how much to increased food consumption.

The increased yield obtained by the Hegelund method was considered hardly more than sufficient to pay for the extra labor involved while the extra stripping was done at a loss.

"If, as is probably the fact, the persistency of the milking habit and the more per-

fect development of the udder are encouraged by either procedure, its adoption has considerable justification, particularly with heifers. This phase of the matter, however, is not included within the scope of the present inquiry. On the other hand, the additional load of dirt, dandruff, hair, dried manure, bacteria, etc., which fall into the milking pail because of the udder manipulation, is a distinct detriment, which, however, the use of some of the covered pails would go far to obviate."

**The economic production and distribution of clean milk,** J. ROBY (*Jour. Amer. Med. Assoc.*, 46 (1906), No. 19, pp. 1430-1432).—This discussion relates particularly to the milk supply of Rochester, New York.

Average monthly counts for 6 years showed the presence of about 100,000 bacteria per cubic centimeter in the milk supply of that city in winter and about 500,000 in summer. Notwithstanding the practical assurance of an increase of 3 cts. per quart in the price of milk, only one farmer was found who was willing to undertake the production of certified milk. In this instance the milk which was produced without expensive equipment showed on an average of 100 determinations the presence of only 3,853 bacteria per cubic centimeter.

In supplying milk to cities the author suggests the use of pails or cans holding about 15 qt. for milking, shipping, and, if desired, for delivering milk. After emptying, the cans are sent to a plant in the city where they are washed by machinery, covered with cheese cloth and a metal cover, and over both a stout canvas cover, and then sterilized by dry heat. The cans are then returned to the farm, where the canvas and metal covers are removed and the milk drawn directly through the cheese cloth into the can. The strainer is then removed and returned to the sterilizing plant with the canvas cover. The cans are at once covered and the milk is cooled by placing the cans immediately in ice water.

**Investigations of the causes of the low Reichert-Meissl numbers of Holland butter,** A. J. SWAVING (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 9, pp. 505-520, *dgm.* 5).—From September 15 to December 19, 5 groups of 4 cows each were fed different rations supplementing grass or hay and linseed cake and determinations were made of the Reichert-Meissl number of the butter made from the milk of each animal.

The content of volatile fatty acids was increased by fodder beets and by lucern silage. Grass silage exerted little or no influence as did also barley meal and sugar when fed as supplements to pasture and linseed cake. The Reichert-Meissl number was lowered by hay and linseed meal alone. While it is not yet clear in what manner the beets influence favorably the Reichert-Meissl number, the author considers that there is now better support for the previously expressed view that easily decomposed carbohydrates, such as sugar, favor the formation of volatile fatty acids only when fed along with materials already undergoing fermentation or easily fermented, such as fodder or sugar beets.

**Bacteriological examinations of butter,** A. REITZ (*Centbl. Bakt. [etc.]*, 2. Abt., 16 (1906), No. 7-9, pp. 193-212).—This is a review of the literature on the occurrence of tubercle bacilli in butter, the bibliography given containing reference to the publications of 73 investigators. The author examined 100 samples of butter obtained in Stuttgart by means of inoculation experiments with animals. The results for 6 samples were inconclusive. In 8 or 8.5 per cent of the remaining samples, tubercle bacilli were found present.

**Casein as an adulterant of butter,** R. RACINE (*Ztschr. Öffentl. Chem.*, 12 (1906), No. 9, pp. 169, 170).—A sample of adulterated butter showed the presence of 5.49 per cent of casein and 24.73 per cent of water.

**The chemical composition of whey and curd during the manufacture of Emmenthal cheese,** G. KOESTLER (*Milchw. Zentrbl.*, 2 (1906), No. 5, pp. 193-224).—According to the results of the author's investigations, the addition of rennet changes the chemical composition of the milk only to the extent of increasing the content of

soluble nitrogenous substances, the inclusion of which in the cheese may be regulated to a certain extent by manipulative methods.

At the time of cutting the curd, the whey shows, for the first few minutes, a decrease in the percentages of fat and proteids due probably to the effect of delayed coagulation, but later the fat content of the whey is increased. The acidity of the whey decreases during the process of manufacture due especially to the disappearance of carbon dioxide. The average of 38 determinations showed a decrease in acidity of 0.41 cc. of one-fourth normal potassium hydroxid per 100 cc. of whey. The total ash in whey decreases during the manufacturing process, the water soluble portion, however, showing an increase. The percentages of phosphoric acid and calcium are decreased.

The paraosein shows no changes in composition while in the kettle. The coagulating power of the whey due to the rennet remains constant until destroyed by the heating. A rapid increase in the acidity of the expressed whey is apparently due to an increase in the concentration of the whey and to lactic-acid fermentation.

**Note on Dutch cheese**, C. H. CRIBB (*Analyst*, 31 (1906), No. 361, pp. 105-111).—Analyses are reported of 25 samples of Edam, Gouda, and other types of cheese imported into England from Holland. Many of these samples showed less than 5 per cent of fat and were consequently considered as made wholly from skim milk. Failure to secure conviction in a trial for adulteration was due to the want of any standard for such cheese.

**Carbonated milk**, L. L. VAN SLYKE and A. W. BOSWORTH (*Abstr. in Science*, n. ser., 23 (1906), No. 592, p. 712).—Fresh milk treated with carbon-dioxide gas under pressure of 60 to 70 lbs. kept from 10 days to 2 weeks at a temperature of 60 to 70° F. and made a very palatable, refreshing beverage. Further work is to be done along this line before the detailed results of the experiments are to be published.

**Artificial milk**, R. RACINE (*Ztschr. Öffentl. Chem.*, 12 (1906), No. 9, pp. 167, 168).—An examination of a so-called artificial milk showed it to be a mixture of sirup and sesame oil emulsified with some proteid substance. This, diluted by the addition of 9 parts of water, is recommended for use in bakeries as a substitute for milk.

**A new wine-cooling machine**, F. T. BIOLETTI (*California Sta. Bul.* 174, pp. 27, figs. 6).—"The machine consists essentially of a copper tube 220 ft. long and 1½ in. in diameter, through which the wine is pumped and which is inclosed in a canvas irrigating hose 4 in. in diameter, through which cold water runs in a direction opposite to that of the wine."

Preliminary tests with small models of this cooler are reported, as are also comparative tests of other cooling machines. It is thought possible that iron may be substituted for copper pipes, although this is not at present recommended, as tests have not been made on a practical scale. The leakage through the canvas hose permits the utilization of the cooling due to evaporation, which, under average working conditions in a dry climate, is estimated as equivalent to the use of water about 3° F. cooler in a machine where this evaporation could not take place.

Tests were made with water and must at different temperatures and with different ratios in the volumes of water and wine. One test of the new machine showed that 1,000 gal. of fermenting wine can be lowered from 95 to 78° in 1 hour by the use of 850 gal. of water at 71.5°. Specifications are given for the construction of a cooler of this type suitable for the use of a cellar making not more than 300,000 gal. of dry wine during a vintage of 30 days with directions for using the cooler in order to secure the greatest efficiency, the latter including formulas and tables for calculating the number of degrees the must or fermenting wine must be cooled and the number of hours the cooler must be used.

**The manufacture of Samshu (Chinese spirit) from Sorghum vulgare**, E. H. WILSON (*Gard. Chron.*, 3. ser., 39 (1906), No. 1005, pp. 194, 195).—This is a brief account of the methods employed in North China and Manchuria in the manufacture of this distilled liquor from sorghum seed.

## VETERINARY MEDICINE.

**Handbook of pathogenic micro-organisms**, W. KOLLE and A. WASSERMANN (*Handbuch der pathogenen Mikroorganismen*. Jena: Gustav Fischer, 1906, Sup., pt. 1, pp. 384, pls. 7, figs. 27).—This is the first supplemental volume to the large work published under the supervision of the editors and contains an account of trypanosomes, pyroplasmiasis, tuberculosis of animals and man, bacterial hematoxins, amebic dysentery, leprosy, and typhoid fever. The latest literature relating to these topics is discussed in connection with bibliographies.

It appears from the review of the literature on tuberculosis that mammalian tubercle bacilli must be divided into 2 types, the human and bovine. It is possible to choose a dose so small that when bovine tubercle bacilli are used in inoculating experimental animals generalized tuberculosis results, while with a dose of the same size of human tubercle bacilli no infection takes place.

**A treatise on the parasites and parasitic diseases of the domesticated animals**, L. G. NEUMANN, trans. by G. FLEMING (London: Baillière, Tindall & Cox, 1905, 2. ed., pp. XVI+697, figs. 365).—The present edition has been revised and edited by J. MacQueen and contains as heretofore, but in a revised form, a detailed account of the parasites affecting domestic animals. These parasites are arranged according to the organs or parts affected as, for example, the skin, digestive apparatus, serous membranes, respiratory apparatus, circulatory apparatus, muscles, connective tissue, bones, nervous system, and genito-urinary organs. An elaborate bibliography of literature relating to this subject is appended to the volume (pp. 647-678).

**Police sanitation of animals**, A. CONTE (*Police sanitaire des animaux*. Paris: J. B. Baillière & Sons, 1906, 2. ed., pp. XII+532).—The government veterinary sanitation in France and her colonies is presented in great detail for the guidance of veterinarians who are concerned with this work.

In a preface to the volume E. Leclainche makes a number of suggestions regarding possible lines of improvement in existing laws. The volume as a whole is divided into three parts relating to veterinary sanitation of France, the colonies, and special information regarding the duties and functions of officials connected with the work.

An elaborate review of the development of the French veterinary laws is presented, together with a discussion of all general sanitary measures relating to the visitation of infected premises, declaration of infection, disinfection, indemnities, supervision of diseased animals, and the general practices of police sanitation.

Special chapters are also given on legislation relating to rabies, cattle plague, contagious pleuro-pneumonia, blackleg, tuberculosis, sheep pox, foot-and-mouth disease, glanders, dourine, swine erysipelas, hog cholera, etc.

**Therapeutic technique**, W. SCHLAMPP (*Therapeutische Technik*. Stuttgart: F. Enke, 1906, vol. 1, pp. VII+419, figs. 171).—In this part of the author's work on the technique of general therapy for veterinarians attention is given to a discussion of therapeutic measures applicable to the skin. The material which naturally falls under this head is classified according to the nature of the remedies used.

Special chapters are devoted to application to the skin of various fluids, salves, pastes, soaps, varnishes, plasters, powders, and paints. The methods of removing the hair are also discussed and an account is presented of treatment of the skin by means of surgical operations, subcutaneous inoculation, irritation of the skin, the use of blisters, and methods adopted for the protection of animals against various parasitic skin infections. The nature and use of a large number of drugs are carefully considered.

**Experimental studies on the permeability of the walls of the alimentary tract of newborn animals for bacteria and proteids**, A. UFFENHEIMER (*Arch. Hyg.*, 55 (1906), No. 1-2, pp. 1-139, pl. 1).—The author conducted a long series of

experiments in feeding new-born animals with virulent cultures of anthrax and tuberculosis, as well as with certain proteids.

In all cases great care was exercised not to injure the mucous membrane in any way so that the infection which followed could be attributed to the permeability of the intestinal walls for the bacteria in question. The experimental animals were guinea pigs and rabbits. By means of tubes and pipettes it was found possible to measure in a very accurate manner the amounts of bacterial cultures fed to the animals. During these experiments it was found that the anthrax bacillus leaves the alimentary tract very readily.

Within 6 hours after feeding the feces contained anthrax bacilli in large numbers, while after 17½ hours they were to be found only in isolated cases. The anthrax bacillus, however, did not lose its virulence in passing through the alimentary tract. It was found that young guinea pigs could be fed very large quantities of virulent anthrax bacilli without causing any infection. Even spore-bearing cultures failed to be pathogenic. When these experiments were carried out according to the requirements of von Behring the guinea pigs remained in perfect health.

In experiments with tubercle bacilli the results were quite different. Within a few days after feeding large quantities of tubercle bacilli, some bacilli were found in the glands of the omentum and liver. When only small quantities were fed, however, the tubercle bacilli could not be found in the glands. Apparently the bacilli passed through the walls of the alimentary tract very rapidly. In certain stages of the process, especially in the cecum and vermiform appendix, sections were made of this material and examined microscopically. Notes are also given on the permeability of the intestines for hemolytic serum, casein, albumen from hens' eggs, and various antitoxins.

**Bacillus necrophorus and its economic importance**, J. R. MOHLER and G. B. MORSE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 91*, pp. 76-116).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R.*, 17, p. 702).

**Report of the chief inspector of stock**, R. E. WEIR (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 6, pp. 527-531).—An account is given of the present government veterinary staff of Western Australia. Brief mention is also made of the prevalence of pleuro-pneumonia, tuberculosis, hog cholera, and Texas fever among animals as well as poisonous plants. The author discusses the present status of horse, cattle, and sheep raising and gives brief notes on the condition of pastures, abattoirs, and the registration of brands.

**Books, memoirs, and articles on tuberculosis**, BOUCHEZ (*Rev. Tuberculose*, 2. ser., 3 (1906), No. 1, pp. 98-120).—A classified bibliography is presented of literature relating to tuberculosis in man and animals. The books and articles referred to are grouped under natural classes according to the organs affected by tuberculosis and into general groups—hygiene, pathology, therapeutics, experimental veterinary medicine, etc.

**Cattle tuberculosis**, H. SESSIONS (*New York: W. R. Jenkins, 1906*, 2. ed., pp. VII+120).—This edition has been practically rewritten and brought up to date by the addition of much new material, particularly with reference to the recent discoveries relating to tuberculosis in cattle. The subject-matter in the volume includes an introduction and chapters on human tuberculosis as related to bovine tuberculosis, cause of the disease, symptoms and diagnosis, tuberculin test, milk inspection, meat inspection, disposal of tuberculous carcasses, and insurance of cattle intended for slaughter.

**Danger of infection with tuberculosis by different kinds of exposure**, E. C. SCHROEDER and W. E. COTTON (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 83*, pp. 44-65).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R.*, 17, p. 699).

**Danger from ingestion of tubercle bacilli killed by heat, A. CALMETTE and M. BAERON** (*Presse Méd. [Paris]*, 1906, No. 15, p. 115).—Young guinea pigs were fed a single dose of 1 to 2 cg. of tubercle bacilli of bovine origin freshly dried and mixed with potato or carrots.

In all cases the guinea pigs died of generalized tuberculosis after about 92 days. Further experiments were then made with bacilli which had been heated to a temperature of 100° C. for a period of 5 minutes. In guinea pigs which were fed such material in doses of 1 to 2 cg. infection took place promptly and death occurred within 37 to 48 days. Hypertrophy of the renal capsules was observed and other lesions resembling those which occur in animals inoculated with repeated large doses of tuberculin. It appears, therefore, that tubercle bacilli killed by heat are not inert bodies for susceptible animals.

**The infectiousness of milk and meat from tuberculous animals, H. PERICAUD** (*Prog. Vét., n. ser.*, 26 (1906), No. 4, pp. 135-137).—Attention is called to the fact that while bovine bacilli are doubtless very virulent for man they are seldom found in the meat of tuberculous animals. As a rule, therefore, such meat can be used without harm. Milk from tuberculous cows, however, must be considered as dangerous and should be sterilized in some manner before being used.

**The frequency of tuberculosis in the dairies of Paris, H. MARTEL** (*Rev. Soc. Sci. Hyg. Aliment.*, 2 (1905), No. 6, pp. 559-563).—Attention has already been called by the health authorities of Paris to the prevalence of tuberculosis among herds which furnish milk for the city. A tuberculin test carried out on 628 cows gave a reaction in 215, or 34.2 per cent, of the animals. On account of this large percentage it is urged that the measures prescribed by the health authorities of Paris be carried out strictly and that further precautions be taken to avoid the subsequent contamination of stables by the introduction of tuberculous animals or otherwise.

**The lymphocyte and tubercle bacillus, J. BARTEL and W. NEUMANN** (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 40 (1906), No. 4, pp. 518-537).—It has usually been assumed that the lymphatic organs and glands must exercise more or less influence upon tubercle bacillus for the reason that this bacillus is carried to so large an extent throughout the organism in the lymphatic system and affects in so large a per cent of cases the lymphatic glands.

Notwithstanding the apparent logical basis for such an assumption the demonstration of any direct influence of the leucocytes upon the tubercle bacillus has proved a difficult matter and in the case of most investigations only negative results have been obtained. In the author's experiments this matter was tested in vitro by placing material from the lymphatic glands in cultures of tubercle bacilli. Such material after varying lengths of time was used for further inoculation of experimental animals.

When the substance of mesenteric glands was used in such tests it was found that animals inoculated with the mixture did not become infected with tuberculosis and showed no infiltration at the point of inoculation or changes in the corresponding lymphatic glands. The substance of the spleen and the lymphatic glands appears, therefore, to exercise an important influence in combining the toxins of tubercle bacillus in essentially the same manner described by Brieger, Kitasato, and others. Tubercle bacilli kept in contact with such material for 22 days were not capable of producing any reaction at the point of inoculation.

**Tuberculosis of the spleen in guinea pigs, C. ACHARD and P. EMILE-WEIL** (*Arch. Méd. Expt. et Anat. Path. [Paris]*, 18 (1906), No. 1, pp. 71-84).—A number of types of splenic lesions were observed in tuberculosis in the guinea pig. The ordinary splenic tuberculosis shows small granulations in the slightly congested parenchyma. In another type the tubercles fuse, causing a filtration of the organ. Hemorrhagic tuberculosis is also observed in some cases. In this type of the disease the spleen is much enlarged, weighing from 5 to 35 gm.

**Experience with von Behring's method of protective vaccination of cattle against tuberculosis**, SCHRICKEK (*Wohnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 7, pp. 121-128).—Von Behring's method of vaccination against tuberculosis has been in practical use for 3 years and the results obtained, therefore, give a good foundation for judging its effectiveness.

The author vaccinated 76 animals by this method without any bad effects, and on evidence of live tubercle bacilli were found in any of the animals which were subsequently killed and examined. It is concluded, therefore, that a protective vaccination of calves under 4 months of age is capable of greatly increasing the resisting power toward tuberculosis and in some cases checks slightly the development of an infection already existing at the time of vaccination.

**The prevention of tuberculosis in cattle**, J. WILSON (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 6 (1906), No. 2, pp. 300-304).—Tuberculosis in cattle according to the author is chiefly spread by means of the air and food. Notes are given on these different methods of infection and on the prevalence of tuberculosis in England. It is estimated that from 5 to 10 per cent of the yearlings in England are infected, 10 to 20 per cent of 2-year olds, and 40 to 60 per cent of adult cows. Attention is called to the danger from mammary tuberculosis in cows and to the use of tuberculin and other methods in the detection and eradication of the disease.

**Anthrax**, D. LAN (*Rev. Facult. Nac. Agron. y Vet.*, 2. ser., 1 (1905), No. 6, pp. 173-176).—Veterinarians in various parts of South America are frequently called upon to deal with outbreaks of anthrax. The author presents a brief account of the course of the disease and of the usual methods of vaccination to immunize animals against it.

**Immunization of the guinea pig and rabbit against anthrax**, F. MARINO (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 6, pp. 306-308).—In the author's experiments it was found possible to vaccinate guinea pigs against anthrax by means of subcutaneous injections of the first vaccine. It was very difficult to produce immunity, however, by intraperitoneal injections.

Guinea pigs which withstood repeated subcutaneous injections of a mixture of anthrax and preventive serum from a rabbit or guinea pig frequently failed to resist the minimum mortal dose of the first vaccine. The normal serum of rabbits mixed with virulent anthrax and injected hypodermically into guinea pigs protects them against the disease.

**The pathological anatomy of glanders**, SCHÜTZ (*Ztschr. Veterinärk.*, 18 (1906), No. 2, pp. 49-63).—This statement was originally prepared in 1882, for the guidance of army veterinarians in determining cases of glanders and for use in diagnosing the disease from pathological material sent to the veterinary school in Berlin. The article in its present form has been recently revised and brought up to date.

**Observations on normal and rinderpest blood**, F. S. H. BALDREY (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 1, pp. 47-69).—In a study of the normal blood it is found that the average number of red blood corpuscles was 7,293,484 per cu. mm. The number varied, however, from 5,600,000 to 9,100,000 and the number of leucocytes varied from 8,000 to 18,000.

In arriving at these averages a large number of counts were made. An examination was also made of the blood of animals which had been bled for the production of a protective rinderpest serum. In these animals it was found that the average number of red blood corpuscles was 3,713,000 per cu. mm. In animals actually suffering from rinderpest the number of leucocytes increases rapidly, rising to 32,000 by the fourth day. The relative proportion of the various elements in the blood is discussed for other diseases as compared with rinderpest.

**Redwater in cattle**, A. E. MERTAM (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 6 (1906), No. 2, pp. 248-260, pls. 3).—This disease, under various names, occurs in North and South America, Africa, Australia, various parts of Asia, and Europe. The

blood parasite which causes the disease is described and notes are given on the symptoms of redwater or Texas fever. A summary account is also given of some of the experimental work done in this country on this disease.

**Cattle tick investigation**, A. MAYER (*Proc. La. Agr. Soc. and Stockbreed. Assoc.*, 1905, pp. 103-110).—Attention is called to the great economic importance of the cattle tick.

This pest not only stunts the development of cattle so that they fail to reach their normal size, but also reduces the market price of cattle raised below the quarantine line. On account of the fact that there are large tick-free areas below the quarantine line cattle raised on such areas must be inoculated or gradually infested with ticks in early life, otherwise they are as susceptible to Texas fever as northern cattle. Considerable reliance is placed in the use of good dips for destroying ticks, but attention is called to the desirability of systematic work in exterminating the tick.

**The etiology of pneumonia**, RIRS (*Berlin. Tierarztl. Wchnschr.*, 1906, No. 8, pp. 129, 130).—Excellent opportunity was had for the study of this disease in horses. It appeared as an infectious disease without special localization in the lungs, and at the outbreak of the symptoms considerable catarrh was noted in the upper part of the respiratory passages, but this was much less pronounced than the catarrhal condition of the duodenum. The temperature rose on the second day to 40.5° C., but fell to normal again within 8 days.

**The persistence of tetanus spores in the animal organism in a latent form**, G. TAROZZI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 40 (1906), Nos. 3, pp. 305-311; 4, pp. 451-458).—Guinea pigs and rabbits were used in the experiments reported in this paper, being inoculated with virulent tetanus cultures which had been kept under aerobic conditions. Only 11 animals were used in the experiments for the purpose of determining whether and how long tetanus spores remain in a latent condition in inoculated animals.

It was found possible to demonstrate the spores in all cases in the liver, usually in the spleen, but, as a rule, not in the kidneys. The author considers that these experiments demonstrate that the tetanus spores pass into the general blood circulation from the point of inoculation and become located in various vital organs where they may persist in a virulent condition for a long period. When removed from such organs they are capable of producing very toxic cultures.

**Infectious diarrhea of calves and liver disease of chickens**, N. S. MAYO (*Estac. Cent. Agron. Cuba Circ.* 22, pp. 4).—Brief notes are given on the distribution of infectious diarrhea in calves together with notes on the rate of mortality and antiseptic treatment to be adopted in preventing the disease. For this purpose the author recommends creolin. A disease of fowls known as little liver is described. The disease is, however, not characterized by lesions in the liver, but by symptoms which closely resemble those of roup. In treating the disease the author recommends the use of potassium permanganate in water at the rate of 1 part to 60.

**Diseases of the stomachs in ruminants**, J. L. WEBB (*Natal Agr. Jour. and Min. Rec.* 9 (1906), No. 1, pp. 1-7).—Cattle are susceptible to various digestive troubles on account of their tendency to eat various indigestible or otherwise harmful substances. In this way hair balls are formed in the stomach and actual lesions may be produced as the result of eating bones or other materials with sharp points. An account is given of impaction of the omasum, gastritis, and parasitic irritation of the fourth stomach. In removing these parasitic worms the author recommends the use of a mixture of 2 oz. arca nut and 30 grains of arsenic made into 10 doses and given daily for a period of 6 days in bran.

**Enzyms in cornstalks and their relation to cornstalk disease**, T. M. PRICE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 84, pp. 66-75).—This is reprinted from the annual report of the Bureau for 1904 (*E. S. R.*, 17, p. 702).

**Observations on Bilharziosis among animals in India,** R. E. MONTGOMERY (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 1, pp. 15-46, pls. 2).—The characters of the genus *Bilharzia* or *Schistosomum* are mentioned in some detail. The form which occurs commonly in cattle is *Schistosomum bovis*.

Particular attention is given in this article to bilharziosis in the horse. The author had opportunity to make a number of post-mortem examinations on affected horses in the plains and hill regions. In addition to the blood parasite which is described as new under the name *S. indicum*, various tapeworms, flukes, and roundworms were found as well as bots. Many of the cases under observation were complicated with surra. The abdominal cavity was found to be in a state of general congestion, as well as the liver and pancreas. The intestinal tract is also the seat of various pathological lesions. The blood parasite may best be obtained from the portal vein of the liver.

A brief bibliography relating to blood parasites in the horse and ass is appended to the article.

**Prevention of sheep pox,** D. D. GARCIA (*Gas. Med. Zool.*, 30 (1906), No. 4, pp. 51-54).—On account of the wide distribution of this disease the importance of practical methods for its control is quite evident. The author calls attention to the use of a preventive and curative serum against sheep pox.

**Dipping as a means of preventing ovine diseases,** F. A. VERNEY (*Natal Agr. Jour. and Min. Rec.*, 9 (1906), No. 1, pp. 11, 12).—Since *Amblyomma lubraeum* is the species of tick which is concerned in carrying heartwater, it is recommended that sheep be dipped for the destruction of this tick in order to control the disease.

**Sheep botfly,** E. THIERRY (*Jour. Agr. Prat., n. ser.*, 10 (1905), No. 37, pp. 344, 345, fig. 1).—The appearance and distribution of this insect are briefly outlined. No curative nor preventive remedies are known which are practical and effective. The palliative measures usually recommended are briefly discussed.

**Some common parasites of sheep** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 6 (1906), No. 2, pp. 295-299, pls. 2).—A discussion is presented of scab mite, sheep ticks, nostril fly, sheep maggots, and biting lice, remedies being recommended for the control of each one of these troubles.

**The life history of the twisted wireworms (*Hæmonchus contortus*) of sheep and other ruminants,** B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 93, pp. 7, figs. 2).—The common stomach worm of sheep is described in its various stages and particular attention is given to a summary of its life history.

It appears that the sheathed embryos of this parasite on grass in infested pastures are capable of great resistance toward cold and desiccation. It is evident, therefore, that the parasite is not destroyed in pastures by the cold weather of winter. The life history of this worm is comparatively simple. The eggs in the feces of infested animals hatch and the young crawl up the stems of grass where they become covered with the sheath and are later taken into the stomach of sheep in grazing. Feeding experiments were carried out which showed that the worm is in a condition to develop in the stomach of sheep when eaten along with grass.

The best method of cleaning up infested pastures consists in burning the grass. It is quite uncertain how long a time must be allowed for the starvation of the embryos and vermifuges can not be depended upon to expel the worms entirely from infested sheep. Experiments are in progress to test the method of raising lambs free from infection.

**Swine plague,** SCHMIDT (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 51, pp. 865-869).—This is a controversial article in which attention is called to the more or less incompatible claims made by various investigators and to the recent discoveries made by the Bureau of Animal Industry in regard to a form of hog cholera caused by a filterable virus. An editorial note is appended to the article in which it is stated that

the subject of swine diseases was not discussed so thoroughly at the recent international veterinary congress as the diseases of other animals.

**The immunization against swine plague by means of bacterial extracts,** J. CITRON (*Ztschr. Hyg. u. Infektionskrank.*, 52 (1906), No. 2, pp. 238-262).—During a long series of experiments it was clearly shown that it is possible by means of a serum obtained from actively immunized rabbits to protect other rabbits, guinea pigs, and white mice against doses of bacteria many times the fatal size. The serum of normal rabbits in smaller quantities did not increase the resisting power of animals into which it was inoculated. The author believes, therefore, that the existence of specific complements in the blood is shown beyond question.

**Through what agency is the *Trypanosoma evansi* carried over from one surra season to another?** A. LINGARD (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 1, pp. 92-112).—Surra is usually fatal in horses, asses, mules, camels, goats, sheep, rats, dogs, and buffaloes. In cattle, however, both in the plains and hill breed, the disease when uncomplicated frequently terminates in recovery.

Cattle may carry the blood parasite for long periods, at least exceeding a year, and are, therefore, the only domestic animals found by the author to be capable of resisting spontaneous inoculation with trypanosomiasis. It is important, therefore, to determine whether cattle affected with this chronic form of the disease are agents in its transmission. As a result of the author's investigations it was found that the blood of cattle affected with the chronic form of the disease, when inoculated into susceptible horses, causes fatal cases of trypanosomiasis, and from such cases the rapid dissemination of the disease may occur.

Camels may also carry the disease for from 9 to 12 months and their blood is likewise pathogenic for horses. It is also found that dogs and cats are susceptible to the disease carried by camels. It is probable, although not definitely demonstrated, that various other wild carnivorous animals may be the agents in carrying the disease. The most rational system of controlling the disease, in the author's opinion, consists in the destruction of all affected horses in which the disease occurs in a virulent form.

**Tibarsa surra,** H. T. PEASE (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 1, pp. 70-91).—Camels have long been known to be susceptible to surra and considerable attention has been given to a study of this disease, with particular reference to its relation to other similar blood diseases. As a result of the author's investigations it is concluded that the form of surra which occurs in camels is due to *Trypanosoma evansi*, the same species which occurs in horses. The disease is often found affecting camels, horses, and mules in the same locality and is apparently due to the same cause.

**A specific serum for *Trypanosoma brucei* and its effect upon *T. gambiense*,** F. K. KLEINE and B. MÜLLERS (*Ztschr. Hyg. u. Infektionskrank.*, 52 (1906), No. 2, pp. 229-237).—A serum was obtained from asses infected with *T. brucei*, which protected mice against fatal doses of this organism. It was observed, however, that the serum did not protect the animal from which it was obtained. Actively immunized trypanosomes inoculated into normal animals soon lost their immunizing property, so that a specific serum was found to be more active in the case of such animals. The serum showed considerable difference in its effect upon *T. brucei* and *T. gambiense*.

**The action of brilliant green on the trypanosomes of nagana,** H. WENDELSTADT and T. FELLNER (*Ztschr. Hyg. u. Infektionskrank.*, 52 (1906), No. 2, pp. 263-281, pl. 1).—Brilliant green was administered subcutaneously in doses of 1 cc. in solution in the proportion of 1:200.

It was found that when experimental animals were thus treated the trypanosomes in the blood were soon affected to such an extent that they would not cause infection when inoculated into another animal. In the course of time brilliant green causes the entire disappearance of trypanosomes in the blood of rats, monkeys, and other experimental animals. The addition of small quantities of arsenic increases

this action. In the process of disintegration of trypanosomes in the blood under the influence of brilliant green a number of peculiar developmental forms were observed.

**Piroplasmoses**, L. PANISSET (*Rev. Gén. Méd. Vét.*, 7 (1906), No. 75, pp. 113-127, fig. 1).—The distribution of these diseases throughout the world is briefly outlined, and descriptive notes are given on piroplasmoses in sheep, horses, and dogs, with an account of the symptoms and lesions in each case, etiology of the various forms of the disease, the agency of ticks in transmitting the disease, and immunization by means of vaccine and serum.

**Piroplasmosis complicated with horse sickness**, THEILER (*Rev. Gén. Méd. Vét.*, 7 (1906), No. 76, pp. 178-181).—Brief notes are given on the occurrence of piroplasmosis among horses after inoculation with the virus of horse sickness. The development of piroplasmosis was due to the use of infected blood.

**The treatment of nail pricks of the horse's foot**, E. L. MOORE (*South Dakota Sta. Bul.* 95, pp. 17-22).—Attention is called to the fact that even slight injuries to the foot may develop serious complications on account of the fact that the foot is constantly in contact with the dirt which may carry bacteria.

In treating cases of nail pricks, followed by the formation of pus, the author obtained excellent results by cleansing the hoof with soap and water, paring away the horn of the hoof from around the affected part, then washing the part in a solution of corrosive sublimate, after which a piece of absorbent cotton is placed on the hoof and the whole firmly bandaged and covered with a thick coating of tar. A little cotton is allowed to extend above the tar bandage, and the corrosive sublimate solution may be applied daily without removing the bandage. This bandage should be left in place for from 7 to 10 days without being disturbed. Detailed clinical notes are given on a number of cases.

**Poisoning of horses by Ornithogalum thyrsoides**, D. HUTCHESON (*Agr. Jour. Cape Good Hope*, 28 (1906), No. 2, pp. 165-172, pl. 1).—A report was previously made on the death of horses from eating this plant and experiments were made in feeding dried plants which proved to be exceedingly poisonous. Further experiments were carried out in feeding the fresh green plant, and these experiments furnished the basis for the present article. It was found that two pounds of the fresh plant were sufficient to cause death in ponies within 2 days. The symptoms of poisoning are briefly discussed and notes are given on the distribution of the plant.

**Examination of the Western Australian poison plants**, E. A. MANN (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 6, pp. 550-561, pls. 5).—Chemical analyses were made of various poisonous plants, including *Gastrolobium calycinum* and other species of this genus, as well as species of *Oxylobium*, particular attention being given to the first-named species. An alkaloid known as cygnin was isolated and was used in physiological tests with guinea pigs. It was found that this alkaloid was fatal for ordinary guinea pigs in hypodermic doses of  $\frac{1}{16}$  to  $\frac{1}{20}$  of a grain.

**The rabies corpuscles of Negri**, J. SCHIFFMANN (*Ztschr. Hyg. u. Infektionskrankh.*, 52 (1906), No. 2, pp. 199-228).—As the result of an extensive study of these bodies the author found that at times they may not be present in the medulla or spinal cord. They are subject to considerable variation with regard to their structure, distribution, and occurrence in the hippocampus and cerebellum, but this variation is independent of the incubation period and number of inoculations which have been made with the virus. After repeated passages of the virus Negri's corpuscles may be entirely absent in the hippocampus and cerebellum.

**The tapeworms of American chickens and turkeys**, B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 85, pp. 268-285, figs. 31).—This is reprinted from the annual report of the Bureau for 1904 (E. S. R., 17, p. 704).

## RURAL ENGINEERING.

**Irrigation investigations** (*Kansas Sta. Rpt. 1905, pp. 26-41*).—This gives the results of investigations of irrigation at Fort Hays and Garden City, Kansas, carried on in cooperation between the Kansas Station and this Office. An account of this work was also given in Bulletin 158 of this Office (E. S. R., 17, p. 705).

**Report of the reconnaissance of the Vaal River**, F. A. HURLEY (*Pretoria: Transvaal Irrig. and Water Supply Dept., 1905, pp. XV + 76, pls. 26*).—This report contains "preliminary descriptions and approximate estimates of the most favorable irrigation schemes practicable" from Vaal River in South Africa, a stream with an annual discharge of about 2,500,000 acre-ft., of which about 65 per cent passes during March floods.

Six projects are included, the two most urgently recommended irrigating 11,800 acres in the Transvaal and 27,800 acres in Orange River Colony. The third and fourth projects would irrigate 60,000 and 20,000 acres, respectively, while the fifth, which would involve an expenditure of about \$25,000,000, would irrigate 400,000 acres, an undertaking not to be considered at present. The sixth project involves only Cape Colony land and is an expensive storage project not fully worked out as yet. The estimated costs per acre runs as follows: \$77, \$63, \$76, \$96, \$50-60, and \$112.

The annual water rate assumed is \$5 to \$7.50 per acre, and the increment in value of land \$50 to \$75 per acre. Maintenance charges are assumed to be about one-fifth of the water rentals, and the net return on the entire investment is estimated as about 6 per cent, except in the sixth project, where it is but 3.3 per cent. If the total increase in value of the land is deducted from the cost of the projects the estimated earnings run 126, 24, 14, 31, and 6 per cent, the fifth project not being included.

The duty of water is estimated on the basis of the severest possible system of cropping with a 3-year rotation of wheat, tobacco, vetches and rye, potatoes, beets and roots, vetches and rye, tobacco, and potatoes. It is further supposed that each irrigation will be 4 in. in depth and that in all 17 irrigations will be required in 3 years, the time of sowing and rainfall being considered. Allowing for 60 per cent loss, 1,000,000 cu. ft. of water must be stored annually for each 5 acres, or about 150 acres per cubic foot per second for a 9-months' season, allowing 20 per cent for roads and waste land. In order to meet the possible requirement of a 4-in. irrigation of the whole area in one month, the estimates for canals are on the basis of 100 acres per cubic foot per second. These estimates are reasonable when compared with the usual duty of 100 acres per cubic foot per second in Egypt, 100 to 300 in India, 120 and 150 under two California canals, and 150 in Spain and Italy.

In reviewing the subject of water rates the author cites as examples tracts in Cape Colony where land and water rent for \$20 to \$22 per acre, while in India the rate is about one-tenth and in Egypt one-seventh of the gross value of crops produced. Regarding the Reclamation-Act projects in the United States he says: "It would seem that the rates have been pitched very low to attract settlers." The rate assumed on the Vaal of \$5 per acre is believed to be less than one-tenth the value of a crop of wheat and corn, the least valuable crops likely to be grown. The total cost to the renter, assuming 6 per cent interest on the value of the land, is considered reasonable, since it falls under \$12.50 per acre annually.

A note by the director of irrigation, W. L. Strange, is included, in which it is stated that \$15,000,000 in produce was imported into the Transvaal in 1904, showing a good market for irrigated products. He points out that the financial failure of irrigation works has usually been due to slow settlement, and that hence large works should be built by the State, which can afford to wait for returns in the form of general prosperity, and that the development of irrigation works should not outrun the normal settlement of the country.

**Agriculture in the valley of the Ahr**, H. DUPAYS and L. LEBRUN (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 8, pp. 241-248, figs. 5).—This article describes briefly irrigation practice in the valley of the Ahr. The irrigation works are simple. The ditches are usually made with rectangular cross section in order that they may take up no more room than is necessary. Water is carried in rectangular flumes made of galvanized iron supported on I-beams. The water is used on meadows, the charges for water being 20 marks per hectare per year.

**Pumping machinery at Mildura** (*Impl. and Mach. Rev.*, 31 (1906), No. 372, p. 1406).—At Mildura, Victoria, water is pumped for 8,000 acres of land. The water is raised at three separate lifts, 20, 25, and 25 ft. Water is pumped at the rate of 26,000 gal. per minute. As a rule there are five irrigations during the year, each lasting 28 days, and the pumps are run at a cost of \$300 per day, or about \$42,000 per year. The fuel is wood. The costs are met by a water tax which varies from 30 to 40 shillings per acre for the land covered. The land receives an average depth of about 22 in. per annum.

**A Hawaiian pumping plant for irrigation** (*Engin. Rec.*, 53 (1906), No. 10, p. 350).—A description of a plant utilizing a small mountain stream by means of impulse wheels and an electric power plant. A method for regulating the speed of the dynamo, motor, and pump has been adopted so that the efficiency is not impaired when the supply in the hills is short. Larger impulse wheels are then used, giving a slower speed to the generator. With an automatic device to keep the field constant the voltage and cycles are diminished in proportion, the motor then falling off in speed without decreased efficiency.

**Canals and ditches**, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 7, pp. 210-212, figs. 8).—This article summarizes foreign and American measurements of percolation of water from ditches, and discusses methods of prevention of losses in canals used for carrying water. It describes methods of preventing seepage losses, including concrete lining, masonry lining of ditches with rectangular cross sections, and the use of flumes.

**The Belle Fourche dam, Belle Fourche project, South Dakota**, R. F. WALTER (*Engin. Rec.*, 53 (1906), No. 9, pp. 307-310, figs. 7).—This dam is one of the largest earth dams in the United States, being over a mile in length and containing 1,600,000 cu. yds. The details of the wasteway, conduits, and gates are described in detail. An unusual feature is the proposed concrete-block facing laid over gravel in lieu of riprap.

**The Belle Fourche irrigation works, South Dakota**, W. W. PATCH (*Engin. News*, 55 (1906), No. 8, pp. 210-212, figs. 5).—A brief account of the project, with a description of the more important structures used.

**The drainage of earth roads** (*Engin. Rec.*, 53 (1906), No. 18, pp. 564-566).—This is an abstract of a bulletin on this subject by Prof. Ira O. Baker, published by the University of Illinois.

It is recommended that tile drains be laid at the side of the road at a depth of 3 or 4 ft., such a drain on one side of an ordinary country road being held to be sufficient. The drain might be more effective in the middle of the road, but the expense of putting it in would be so much greater that a drain at the side of the road is preferred. There is no limit to the steepness of the grades on which tile drains may be used, but the grade should not be less than 2 in. per 100 ft. It is important that the tile drains should have a free outlet. The cost of putting in 5-in. tile drains is given as \$200 to \$250 per mile.

Side ditches are necessary whether the tile is used or not. These should be broad rather than deep, with easy slope toward the road in order that vehicles may not be harmed if they get into these ditches. Water should not be carried long distances in these side ditches, but outlets should be provided at short intervals. Roads should be crowned sufficiently to provide for rapid surface drainage into the side ditches.

Where the roads are in excavation catch waters should be provided to keep drainage water off of the road. For maintaining the surface of roads in good condition, harrowing or dragging with a railroad rail, heavy timber, or split log is recommended.

**The mixing of concrete**, E. McCULLOUGH (*Sci. Amer. Sup.*, 61 (1906), No. 1580, pp. 25316-25318).—The author states briefly the advantages of concrete over stone, calls attention to the necessity of thorough mixing, and compares hand mixing with various types of mechanical mixers. He favors the cube mixer.

**Report of the commission on alcohol appointed by the minister of finance** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 15, pp. 454, 455).—This commission, appointed to inquire into proper legislation for controlling the manufacture and sale of alcohol, recommended in regard to denaturized alcohol that: (1) In order to avoid adulteration the dealers should be required to label their goods in a conspicuous manner "denaturized alcohol, guaranteed 90 degrees;" (2) denaturized alcohol should have the benefits of reduced rates of transportation granted to refined petroleum; (3) that the vessels for denaturized alcohol which are returned empty to the shipper should be carried free on the state railroads, or pay the rates charged for merchandise of the fourth or fifth class on private lines; (4) so far as possible the formalities observed in the distribution, storage, and sale of denaturized alcohol should be simplified.

## MISCELLANEOUS.

**Sixteenth Annual Report of Arizona Station, 1905** (*Arizona Sta. Rpt. 1905*, pp. 26).—This contains the organization list of the station, a review of the work of the station during the year by the director, a financial statement for the fiscal year ended June 30, 1905, and departmental reports, some of which are noted elsewhere.

**Annual Report of Idaho Station, 1905** (*Idaho Sta. Rpt. 1905*, pp. 48).—This includes a financial statement for the fiscal year ended June 30, 1905, a report of the director on the work and publications of the station during the year, and experimental work and meteorological observations abstracted elsewhere in this issue.

**Eighteenth Annual Report of Indiana Station, 1905** (*Indiana Sta. Rpt. 1905*, pp. 46).—This consists of the report of the director and heads of departments, a list of periodicals received by the station library, a subject list of the bulletins of the station to date, and a financial statement for the fiscal year ended June 30, 1905. The report of the director contains a list of the cooperative experiments in progress July 1, 1905, and the report of the chemist an analysis of a sample of cattle food which was found to contain 96.73 per cent of sodium chlorid. The report of the horticulturist is noted elsewhere.

**Eighteenth Annual Report of Kansas Station, 1905** (*Kansas Sta. Rpt. 1905*, pp. 55).—This contains a financial statement for the fiscal year ended June 30, 1905, a report of the council including abstracts of bulletins issued during the year, brief summaries of the work of the different departments not reported upon in bulletins, a report on the work of Fort Hays Branch Station, a statement concerning cooperative experiments with this Department, a subject list of station publications issued to date, and an index to the report and the bulletins issued during the year.

**Fourteenth Annual Report of Kentucky Station, 1901** (*Kentucky Sta. Rpt. 1901*, pp. XV + 308).—This report, only recently issued, contains a financial statement for the fiscal year ended June 30, 1901, brief reports of the director and heads of departments for that year, miscellaneous chemical analyses and meteorological observations noted elsewhere, and reprints of Bulletins 91-97 of the station on the following subjects: Enemies of cucumbers and related plants (*E. S. R.*, 13, p. 368); experiments with potato scab (*E. S. R.*, 13, p. 360); the food of the toad (*E. S. R.*, 13, p. 325); grapes (*E. S. R.*, 13, p. 355); diseases of nursery stock (*E. S. R.*, 13, p. 571); rabbits and their injuries to young trees (*E. S. R.*, 13, p. 531); wheat (*E. S. R.*, 13, p. 737); commercial fertilizers (*E. S. R.*, 13, p. 730); the Hessian fly (*E. S. R.*,

13, p. 968); dangerous mosquitoes in Kentucky (E. S. R., 13, p. 971); poisonous and edible mushrooms (E. S. R., 13, p. 920), and commercial fertilizers (E. S. R., 13, p. 935).

**Fifteenth Annual Report of Kentucky Station, 1902** (*Kentucky Sta. Rpt. 1902, pp. XVI+349*).—This contains a financial statement for the fiscal year ended June 30, 1902, a report of the director on the work of the station, including the fertilizer and food-control work, miscellaneous chemical analyses and meteorological observations noted elsewhere, and reprints of Bulletins 98-104 of the station on the following subjects: Kentucky forage plants (E. S. R., 14, p. 241); experiments with oats (E. S. R., 14, p. 242); inspection and analyses of foods (E. S. R., 14, p. 277); a comparison of feeds for pigs (E. S. R., 14, p. 283); analyses of commercial fertilizers (E. S. R., 14, p. 558); Hessian fly experiments (E. S. R., 14, p. 987), and analyses of commercial fertilizers (E. S. R., 14, p. 953).

**Eighteenth Annual Report of Louisiana Stations, 1905** (*Louisiana Sta. Rpt. 1905, pp. 32*).—This contains reports of the Sugar Station at Audubon Park, New Orleans, the State Station at Baton Rouge, and the North Louisiana Station at Calhoun; statements concerning the work of the State geological survey and the United States Geological Survey in the State, and a financial statement for the fiscal year ended June 30, 1905.

**Finances, meteorology, index** (*Maine Sta. Bul. 124, pp. 227-268+VII*).—This bulletin consists of meteorological observations noted elsewhere, a financial statement for the fiscal year ended June 30, 1905, an index to the station reports for 1901-1905 and to bulletins 112-124, which collectively make up the twenty-first annual report of the station, and announcements and notes concerning the station.

**Eighteenth Annual Report of Michigan Station, 1905** (*Michigan Sta. Rpt. 1905, pp. 81-539*).—This contains a financial statement for the fiscal year ended June 30, 1905; reports of the director and heads of departments, summarizing briefly some of the results of experiment station work during the year; meteorological observations noted elsewhere; and reprints of Bulletins 217-231 and Special Bulletins 24-33 of the station, which have already been noted.

**Report of work at McNeill Branch Station, 1904**, E. B. FERRIS (*Mississippi Sta. Bul. 87, pp. 16*).—Brief notes are given on weather conditions during the year and experiments with fruits, vegetables, and field crops are reported. The experimental work is abstracted elsewhere in this issue.

**Eighteenth Annual Report of Vermont Station, 1905** (*Vermont Sta. Rpt. 1905, pp. 245-466*).—This includes the organization list of the station, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1905, a report of the director, abstracts of Bulletins 109-116 of the station issued during the year, and numerous articles abstracted elsewhere in this issue.

**Abstract of Eighteenth Annual Report, 1905** (*Vermont Sta. Bul. 119, pp. 19-64, fig. 1*).—This is a résumé of the annual report of the station noted above.

**Crop Reporter** (*U. S. Dept. Agr., Bur. Statist. Crop Reporter, vol. 7, Nos. 11, pp. 95-102; 12, pp. 103-110*).—These numbers contain the usual statistics on the condition of crops in the United States and foreign countries and special articles on imported tobacco, exports of butter, imports of agricultural products into the United Kingdom, damage to the Cuban tobacco crop, the British market for Indian corn, and other topics.

**Experiment Station Work, XXXIV** (*U. S. Dept. Agr., Farmers' Bul. 251, pp. 32, fig. 1*).—This number contains articles on the following subjects: American sugar-beet seed, stimulants for seeds, profits from spraying potatoes, winter-injured fruit trees, durum wheat, fertility of eggs, indoor v. outdoor feeding of steers, roughage for steers, cheap dairy rations, and cotton-seed meal for hogs.

## NOTES.

---

**Colorado College.**—A short course in horticulture was provided for by the State board of agriculture at its last meeting, to be held at Delta some time during the coming winter. This was done with the understanding that there would be at least fifty students regularly enrolled. One hundred have already signed the enrollment.

**Delaware Station.**—At a recent meeting of the board of trustees A. T. Neale was relieved of duty as director of the station, and was appointed in charge of the departments of agronomy and animal husbandry. This change went into effect July 1. A successor to Dr. Neale as director has not yet been elected.

**Georgia Station.**—Under the provisions of the Adams Act, the station proposes to inaugurate two new departments, i. e., departments of plant breeding and pathology (R. J. H. De Loach, of Athens, Ga., in charge), and of bacteriology. J. F. Monroe, of Guelph, Ontario, and P. N. Flint, of Cement City, Mich., have been made assistants in the departments of horticulture and animal industry, respectively.

**Idaho University and Station.**—Work is in progress on the new agricultural building, which is to be a brick structure 65 by 125 ft. in size and 3 stories high. The building will afford accommodations for the agricultural work of the university as well as the experiment station.

The people of Caldwell have donated 320 acres of land for an "auxiliary station," where experiments may be carried on under irrigation and dry-land farming.

**Illinois University and Station.**—The agricultural building at the university is undergoing an overhauling to secure space made necessary by the unexpected increase in students and by the demands of the station. The dairy department is now occupying the rooms made vacant by the removal of the household science department to the woman's building; the stock-judging room is being floored to provide an additional class room, and laboratories throughout the building are to be doubled in size.

A farm mechanics building, 100 ft. square and 2 stories high, is being erected. This will enable the entire southeast wing, which has been used for the farm mechanics work, to be fitted up for soil physics and crop work. When the agricultural building was erected there were but 19 students in agriculture and 7 instructors and investigators. Now the students have increased to 430, and there are 44 employees in the college and station—all within the space of 6 years.

**Louisiana University and Stations.**—E. Rosenthal, from the agricultural college, Madison, Wis., has been elected dairyman of the station at Calhoun. J. G. Lee, jr., of the class of 1906 of the university, has been placed in charge of feeding experiments at the station at Calhoun. H. R. Fulton has been elected to the position of plant pathologist at the station at Baton Rouge. Mr. Fulton is a graduate of the University of Mississippi, took his master's degree at Columbia, Mo., and has been taking work at Harvard the past year. H. J. Milk, of Watertown, N. J., has been elected bacteriologist of the stations, and will devote his time to the investigation of animal diseases.

The legislature passed a bill giving \$50,000 for a new chemical laboratory for the university. The foundation is now being laid for a building to be devoted to experimental engineering.

**Missouri Station.**—Leonard Haseman, recently connected with the Florida University and Station, has been appointed assistant in entomology. C. R. Crosby, assistant in entomology, has gone to the New York Cornell Station.

**Cornell University and Station.**—T. L. Lyon, of the Nebraska University and Station, has been appointed agronomist in the station. W. A. Stocking, jr., for several years past connected with the Connecticut College and Storrs Station, has been elected assistant professor of dairy bacteriology in the college of agriculture.

The next winter dairy course at the university will open Thursday, December 6, and close Wednesday, February 27, 1907. This is about four weeks earlier than the course has been started heretofore. The change is made possible by the new dairy building and increased number of instructors for next year, which will permit both the long and short courses to be in progress at the same time. Nine-tenths of last year's class expressed themselves in favor of the earlier date.

**Oklahoma College and Station.**—At a recent meeting of the board of regents, A. T. Kruse, of Geary, Okla., appointed to succeed H. G. Beard, resigned, was elected treasurer of the board. E. H. Riley was relieved of station work to give all of his time to the school of agriculture and domestic economy. Roy C. Potts, a graduate of the Michigan Agricultural College, was appointed assistant in dairying in the college and station, vice C. H. Tourgee.

**Texas College and Station.**—John A. Craig resigned his position as dean and director July 1, and will give his attention to stock raising.

**Vermont University and Station.**—N. J. Giddings, a graduate in the agricultural department of the class of 1906, has been elected assistant botanist in the station to succeed W. J. Morse, who, as previously noted, resigned to accept a position at the Maine Station. H. A. Edson, a graduate of the chemical department of the class of 1906, assumes some of Professor Morse's college duties, and incidentally does some work for the station along botanical lines.

**Virginia Station.**—A large experimental orchard of dwarf apple trees on Doucin stocks was planted the past spring to determine the value of dwarf trees for commercial work. This orchard contains representatives of all the leading commercial varieties. This is the first orchard of its kind in the South, and the outcome is awaited with interest. The value of dwarf trees in relation to the horticultural operations of pruning, spraying, and harvesting is obvious, but questions of yield and hardiness in this climate are unsettled.

Extensive cooperative investigations relative to tobacco have been arranged for between the Bureau of Soils of this Department and the station. B. G. Anderson and W. L. Owen, graduates of the college of agriculture, have been appointed as the station's representatives to take charge of the cooperative work in the dark-tobacco belt at West Apportion and in the light-tobacco belt at Chatham.

**U. S. Department of Agriculture.**—Dr. C. F. Langworthy, who has long been associated with the nutrition investigations assigned to this Office, formerly directed by Prof. W. O. Atwater, has been given general charge of this work, under the supervision of the director of the Office.

Dr. Ulysses G. Houck has been selected to have immediate charge of the new meat inspection work in the Bureau of Animal Industry. Dr. Houck was formerly a traveling inspector in the field. He will hereafter be located in Washington.

Dr. R. P. Steddom, chief of the Inspection Division of the Bureau of Animal Industry, will have immediate charge of the work on tick eradication provided for in the new appropriation act, and of the field work on the eradication of scabies in sheep and cattle.

Dr. Charles A. Browne, jr., recently chemist at the Louisiana Sugar Station at New Orleans, has been appointed chief of the sugar laboratory in the Bureau of Chemistry, this Department. He entered upon his duties early in July.

A. J. Pieters, in charge of the seed and plant introduction in the Bureau of Plant Industry of this Department, has announced his intention of resigning from the Department service in the early fall to engage in private business.

**Cooperative Experiment Association of the Great Plains Area.**—The first annual meeting of the Cooperative Experiment Association of the Great Plains Area was held at Lincoln, Nebraska, June 21–22, 1906. This association consists of those members of experiment stations who are interested in field-crop work in the States of North Dakota, South Dakota, Nebraska, Oklahoma, and the north of Texas, together with representatives of the Bureau of Plant Industry of this Department who are interested in experiments in crop rotation and tillage in that region. The association was organized at the time of the annual convention of the Association of American Agricultural Colleges and Experiment Stations at Washington in 1905, with B. T. Galloway as president and E. C. Chilcott as secretary.

This first annual meeting at Lincoln was a very successful one, both in point of attendance and the interest and enthusiasm manifested. Eleven members of the Department of Agriculture were present and about fifteen experiment workers. The following were among the papers read: Effect of Crop Rotation on Soil Fertility, J. H. Shepperd, North Dakota; Comparative Value of Corn and Summer Fallow in Alternation of Wheat, John S. Cole, South Dakota; Drought Resistance of Sorghum Crops, A. H. Leidigh, Bureau of Plant Industry, Amarillo, Texas; Seed Selection Essential in Crop Production under Semiarid Conditions, W. H. Olin, Colorado; Proposed Physical Investigations in connection with the Cooperative Cultivation Experiments, L. J. Briggs, Bureau of Plant Industry; Crop Production in Western Kansas, O. H. Elling, Fort Hays, Kansas. These papers and many other subjects of similar nature were informally discussed.

The visiting members were given an opportunity of seeing the work of the Nebraska Station, and a luncheon was tendered them by the Lincoln Commercial Club. Director E. A. Burnett was elected president for the ensuing year, and E. C. Chilcott, reelected secretary. Manhattan, Kansas, was chosen as the place of holding the next summer meeting.

**Society for Horticultural Science.**—At the Cornell meeting of the society, June 27 and 28, W. T. Macoun spoke on The Relation of Winter Apples to Hardiness of the Tree. To withstand a test winter at Ottawa, a tree or shrub must ripen its wood early. Winterkilling is liable to be more severe after a season when the growth has been strong than when it has been short. The more moderate the climate where a variety originates, the less resistant is it to winterkilling. The hardiest varieties of apples are those that have originated in Russia and are summer or autumn varieties. This is because they ripen their wood most thoroughly, whereas winter varieties continue growth later in the season. The basis for the production of the desired winter apple for the North should be a variety which has withstood test winters in a similar climate and is also the latest keeper of such varieties.

William Stuart presented a general discussion of the use of anesthetics in the forcing of plants, and summarized his own experiments with rhubarb. (See E. S. R., 17, p. 250.)

In a paper on Pollination Methods, S. W. Fletcher presented a symposium of his own experience and that of a considerable number of other plant breeders. The ideal time to emasculate blossoms is as late as possible before the anthers dehisce, but may be done when the buds are still quite small. If complete accuracy is not essential, and when working on blossoms that do not mature stamens and pistils simultaneously, the blossoms need not be emasculated. In crossing, select mature trees of moderate growth and perfectly sound. On such trees select buds borne high up on the outside of the tree on well-nourished branches on the side of the tree opposite from the direction of severe prevailing winds. As to the instruments for emasculating, in the majority of cases a small scalpel is to be preferred, especially for the stone and pome fruits. As to the location of the cut, the majority opinion is that it should be made at the insertion of the stamens above the nectary, though the author

himself prefers to make it as high up as possible. The safest time to pollinate is near the beginning of the receptive condition of the pistils or perhaps twenty-four hours before. A receptive stigma usually glistens when it catches the sunlight and in most fruits it is beginning to be slightly brownish. Brush pollinating is often most practicable when many blossoms must be pollinated in a short time. For our common trees, however, some workers use the thumb or forefinger. As to the percentage of successes, seven pollinators of experience placed their averages variously at from 50 per cent down.

Some phases of pollination were presented by N. O. Booth. The period during which fresh pollen is available for study may be lengthened by forcing twigs in the laboratory. If pollen is taken from the orchard at the normal blooming season it is advisable to take twigs with still unopened buds and let them open indoors. This assures freedom from foreign pollen. Very few apple varieties have the pollen all good and none so far all bad, most varieties showing different proportions of mixed forms. Pollen from the same tree may differ with the condition of the tree. Tompkins King and Esopus Spitzenburg among others have notably weak pollen and are successfully raised only in neighborhoods where conditions are favorable for pollen production. Varieties with particularly strong pollen, as Jonathan and Ralls, are of wide adaptation and are often liable to overbear, the fruits being consequently undersize.

F. W. Card presented a symposium of experience as to the advantage of double-working apples on vigorous stocks. The value of top-working to increase hardiness of stock in a trying climate is unquestioned. It markedly reduces injury from certain diseases. Northern Spy, especially, promises to reduce injury from the woolly aphid in the South. Weak-growing varieties are benefited by the practice. Early bearing can be promoted by top-working on a weak stock, although at the expense of productiveness and doubtless of longevity. But for ordinary varieties in favorable regions the advantages of top-working are outweighed by the disadvantages.

Earle J. Owen discussed The Importance of Selection in Plant Breeding, citing several striking examples of its application.

L. C. Corbett raised the query, What is to be the Future Application of the Term Horticulture? To the already recognized subdivisions of horticultural interests in America, namely, olericulture, pomology, floriculture, and landscape gardening, the author would add plant breeding and plant propagation. Under the latter head is comprised nursery work and the increasing of annual plants from seed or from herbaceous cuttings.

H. J. Eustace gave an account of investigations on apple decays in commercial cold storage. Several varieties of apples were inoculated with black rot, brown rot, bitter rot, soft rot or blue rot, and a species of *Alternaria*, and at once put in cold storage at a constant temperature of 30 to 32° F. At the end of two months none of these diseases had developed except the soft or blue rot. Later, when the inoculated fruit was taken out of storage, the other diseases also developed, showing that the low temperature of the cold storage simply retarded the fungi in their development but did not destroy them. In another experiment, where the temperature ranged from 37 to 56°, decays developed slowly, except the soft rot; but when the temperature ranged from 54 to 65.5° all decays developed and in most cases very rapidly. Peaches similarly inoculated and held in cold storage two weeks developed decays in about one-half of the specimens.

Prof. W. R. Lazenby read a paper on the use of colored cloth in shading plants. Cabbage, tomato, lettuce, and geranium plants, as well as seeds of corn, peas, beans, and radishes were grown under ordinary white cheese cloth shade, as well as cheese cloth colored black, red, blue, and yellow. Corn and bean seeds came up most readily under the black cloth, but the plants under both black and red cloth soon

began to show weakness and decline in rate of growth. The early shading of rhubarb with black cloth gave excellent results in lengthening the petiole and diminishing the size of the leaf blade. On the whole, the observations indicate "that black hanting may be profitably used as a shade in early spring and possibly at a later date on certain crops, like celery, cauliflower, etc. It may also hasten the maturity of certain vegetables, like tomatoes, when used after the plants or fruit are well developed." Other benefits from shading are the protection of the plants from frost, and from certain insects, like the radish fly and beetle.

II. P. Gould described the recording of phenological data for pomological uses as carried on by the U. S. Department of Agriculture for several years past.

Abstracts of L. H. Bailey's address on The Field for Experiment in Horticulture and John Craig's paper on Plant Growing by Artificial Light were not obtained.

**Forestry Instruction at Armstrong College.**—The forestry branch of Armstrong College, Newcastle-on-Tyne, has been given charge of the local management of Chopwell Woods in the county of Durham. These woods are within a few miles of the college and contain nearly 900 acres of larch, spruce, Scotch pine, oak, ash, and other trees, most of which were planted about 50 years ago. A house is being built in the woods for the college lecturer in forestry, and arrangements made for the holding of short courses for practical foresters. It is believed that this addition to the college will make it one of the most favorable centers for forestry instruction in the United Kingdom.

**Macdonald College.**—The New York *Evening Post* is authority for the statement that Sir William Macdonald has completed arrangements for transferring the new Macdonald College, at St. Anne de Bellevue, near Montreal, which was established by him, to McGill University. The property is valued at between \$2,000,000 and \$3,000,000, and has a fund amounting to \$2,000,000. It is the founder's wish that it should rank as a college of McGill University.

**A New Sugar School.**—A professional sugar school was opened at St. Ghislain, Belgium, May 1, 1906, with 12 students in attendance. The course of study includes the following subjects: Physics and general chemistry; analytical and applied chemistry; sugar technology, sugar chemistry, and sugar legislation; general mechanics and industrial electricity; mathematics; sugar accounts; geometrical drawing, industrial drawing, and industrial economy. The course covers two years and leads to a diploma.

**Irish Scholarships in Agriculture.**—The Department of Agriculture and Technical Instruction for Ireland offers scholarships at the Royal College of Science in Dublin and the Albert Agricultural College, Glasnevin, each scholarship to include free tuition for one year, a third-class railway fare to and from college, and either a maintenance allowance of \$5.00 a week if in attendance at the Royal College of Science or free board and lodging at the Albert Agricultural College. The scholarships are good for one year, but may be renewed for two or three years to enable students to complete the agricultural course.

**A Summer School Course in Children's Gardens.**—The New York University is conducting a six weeks' course in children's gardens in connection with its summer school, which opened July 2. The course is under the direction of Henry Griscom Parsons, Assistant Director of Children's Gardens in New York, and about 25 young women have been enrolled.

**School Gardens in England.**—According to a recent report in the *Agriculturist Economist* there are in Surrey County, England, under the control of the Surrey Education Committee, 61 sets of children's gardens attached to the elementary schools, where no less than 1,000 boys are being taught practical gardening. Tools and seeds are supplied and a capable instructor is employed.

**Miscellaneous.**—The degree of doctor of science was conferred upon Dr. A. C. True, director of this Office, by Wesleyan University.

Dr. D. E. Salmon, formerly chief of the Bureau of Animal Industry of this Department, has accepted an offer of the Government of Uruguay to organize a bureau of animal industry for that government, and will proceed to that country next December.

Prof. William Schlick, of St. John's College, Oxford, has been constituted professor of forestry.

W. P. Wright, horticultural instructor in Kent County, has been appointed superintendent and lecturer of the horticultural department of the Southeastern Agricultural College at Wye, England. A definite course along this line is to be established at the college.

The Cuban Government has recently instituted an official publication of the secretary of agriculture, industry, and commerce, entitled *Boletín Oficial de la Secretaría de Agricultura, Industria y Comercio*, Vol. I, No. 1 of which has been received. It is announced that the experiment station will be a contributor to this publication, and the first number gives the full organization of the station, which includes 21 persons.

*Le Bambou* is the name of a new French monthly publication, which is to be devoted entirely to the study, culture, and uses of bamboo. It is published at Mons, Belgium, by the editor, Jean Houzeau de Lehaie. The first number was issued January 15, and contains 40 octavo pages.

The Rhine Province Dairy Institute at Zulpich was removed to Griethausen, near Cleve, on April 1, 1906.

# EXPERIMENT STATION RECORD.

VOL. XVII.

AUGUST, 1906.

---

No. 12.

The second session of the Graduate School of Agriculture, held at the College of Agriculture of the University of Illinois, July 2-28, was a marked success from beginning to end. As is generally known the graduate school has been adopted by the Association of American Agricultural Colleges and Experiment Stations, and the colleges represented in that organization tax themselves for its support. In its general management of the enterprise, the association is represented by its standing committee on graduate study, of which Director L. H. Bailey, of Cornell University, is chairman. The University of Illinois very generously extended an invitation to hold the school under its auspices this year, and its success was due in no small measure to the excellent facilities afforded by the College of Agriculture and the efforts of its personnel. Dr. A. C. True, Director of the Office of Experiment Stations of the U. S. Department of Agriculture, was again selected as dean of the school, and Prof. Eugene Davenport, dean of the College of Agriculture of the University of Illinois, acted as registrar. Courses were given in agronomy, horticulture, plant physiology and pathology, zootechny, and plant and animal breeding, with special reference to the production of plants and animals suited to the conditions in the Mississippi Valley and the Great Plains. These included lectures and seminars, but no laboratory exercises.

The faculty consisted of 35 of our leading agricultural teachers and investigators, including 5 officers of the U. S. Department of Agriculture, 12 members of the faculty of the College of Agriculture of the University of Illinois, and 18 professors and experts from 16 other agricultural colleges and experiment stations. Aside from these there were several outside men who lectured at the school, among whom were the statistician of the Union Stock Yards at Chicago, representatives of a large commission house in Chicago and of Swift & Co., Maj. David Castleman, who spoke on the breeding of saddle horses, and Mr. N. H. Gentry, the famous breeder of Berkshire pigs.

The total enrollment of the school was 131, of whom 91 were classed as students. These came from 34 States and Territories. Hungary was represented by a professor from the University of Budapest, and

there were three students from India. In addition, there were a considerable number of persons who came as visitors, to attend the exercises for a few days, who were not registered. The attendance, therefore, considerably exceeded that of the previous session, at Ohio State University, at which 75 students were registered.

The opening exercises of the school were held on the evening of July 4, when the school was welcomed to the University by Dr. T. J. Burrill, vice-president of the University. Prof. L. H. Bailey presided and made an address in which he pointed out the need of a comprehensive system of agricultural education comprising institutions or departments for research, graduate study, college courses, extension work, and secondary and elementary courses. The graduate school is needed to aid in the more complete establishment of such a system and to stimulate workers in our agricultural institutions to more thorough study and research.

Dr. A. C. True gave a short history of the graduate school and pointed out the great development of agricultural education and research in this country since the first session of the school was held four years ago. He also called attention to the pressing need for more trained workers in different branches of agricultural service. The claim was made that the battle for adequate recognition of agriculture in our higher institutions of learning is essentially won and that our leading educators are convinced that agriculture in some form should constitute part of the industrial element of public school education. It was pointed out that so great is the public interest in agricultural education and research that funds are coming to our agricultural institutions fully as fast as they can be utilized, and that a very great responsibility is being laid on our agricultural teachers and scientists to make the best use of the money put in their hands.

A paper by Dr. H. W. Wiley, Chief of the Bureau of Chemistry of the U. S. Department of Agriculture, was also presented, in which the meager opportunities for study along agricultural lines in preparation for the doctor's degree at our leading universities were shown. These were contrasted with the wider opportunities for such work offered in the German universities and the greater extent to which advanced study in agricultural lines is encouraged. Dr. Wiley declared that "there are no problems of a strictly scientific character which at the present time have more intimate relations to the welfare of the people than those which are connected with agriculture. The field of research also in this region is more fruitful, the number of problems greater, and the opportunities for discovery wider than in almost any other field of scientific investigation. The establishment of agricultural colleges and experiment stations is giving proper training to a vast body of young men, many of whom ought to enter the university and continue

the studies of their college days. . . . What the friends of agriculture should ask is that in the future our great universities should recognize agricultural science as one of the leading branches to which attention should be paid in graduate studies."

Several conferences and informal meetings were held during the session of the school, and a National Association of Dairy Instructors and Investigators was formed. A conference for the discussion of general questions relating to the organization of agricultural education and research was held July 7. Dean Davenport outlined the organization of the College of Agriculture of the University of Illinois. The system followed there involves the division of authority and work in such a manner that definite responsibility is laid on officers in the several departments and full credit is given for each man's share in the work. Questions involving "team work" are discussed at meetings of the workers, and every effort is made to secure full agreement on plans before their execution is attempted. In order to secure financial and moral support for the college and station the farmers' organizations throughout the State are taken into confidence, and the responsibility for the proper maintenance of the institution is laid on their shoulders.

Professor Bailey argued in favor of the establishment of regular provision for agricultural studies leading to the doctor's degree in our universities and would make this a matter to be controlled by the university rather than by the college of agriculture. He also favored the simplification of degrees and would have Ph. D., M. S., and B. S. (or M. A. and B. A.) the only degrees to be conferred in course. This suggestion met with much approval from members of the graduate school.

Dr. W. H. Jordan, director of the New York State Experiment Station, spoke very earnestly of the need of more thorough scientific research along agricultural lines, and impressed his hearers with the great importance of maintaining the strictest integrity in making and recording agricultural investigations.

Dr. W. O. Thompson, president of Ohio State University and one of the founders of the graduate school, gave a brief account of the origin of the school, and expressed his strong belief in its value as an aid to broadening and strengthening our system of agricultural education. He predicted that it would have a career of increasing success and usefulness. Dr. Brown Ayres, president of the University of Tennessee, spoke from the standpoint of one interested in general educational advancement, and emphasized the importance of the movement for the development of a thorough system of agricultural education.

A conference on extension work in agriculture was held July 21, at which great interest in this feature was developed. Resolutions

favoring the aid of the Office of Experiment Stations in this direction were adopted.

A meeting of dairy instructors and investigators July 17-19 resulted in the formation of a national organization, as mentioned above. At this meeting a regular programme was presented, covering the whole range of dairy teaching and experimentation. The papers and discussion brought out the urgent need of scientific investigation to solve many practical problems in dairying and in the feeding of dairy cattle. Emphasis was placed on the demand for more and better trained men in dairy work, and on raising the standard of dairy instruction. Prof. R. A. Pearson, of Cornell University, was elected president of the association, C. B. Lane, of the U. S. Department of Agriculture, secretary-treasurer, and committees were appointed upon various topics.

Informal meetings were held several evenings at which questions relating to various phases of agricultural education were discussed. Among these were the methods of teaching agronomy, the organization of secondary and elementary courses in agriculture, and the science of agriculture as a basis for the organization of a system of agricultural education. These meetings were to some extent a continuation of the daily sessions and seminars. This atmosphere of discussion of matters of fundamental importance in agricultural education and research was probably one of the most beneficial features of the school.

On Saturday, July 14, about 70 members of the school visited the estate of the Funk Bros., near Bloomington, Ill., comprising about 25,000 acres, where crop and animal production on a large scale was seen under the best conditions, as well as considerable experimental work in breeding oats and corn.

When news came of the death of Hon. H. C. Adams, the school adopted resolutions expressing their appreciation of the services rendered to the cause of agricultural education and research by Mr. Adams, in securing the passage of the act "which will forever bear his name and associate him in the minds of our people with Senator Morrill, of Vermont, and Representative Hatch, of Missouri, through whose wise statesmanship our agricultural colleges and experiment stations have been established and maintained."

The interest in the work of the school was well sustained throughout the session. There was considerable going and coming of students, a few even registering during the last week. Even those who stayed only a few days seemed to feel that they had received inspiration and information which made their coming to the school worth while. The students were unanimous in their expressions of the benefits and the broadening influence of the school, and in the general hope that another session might be held two years hence.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY.

**The examination of materials important in agriculture and the industries,** J. KÖNIG (*Die Untersuchung landwirtschaftlich und gewerblich wichtiger Stoffe*. Berlin: Paul Parey, 1906, 3. ed., rev., pp. 1100, pl. 1, figs. 352).—This is the third revised edition of this practical handbook of methods of examination of soils, manures and fertilizers, ashes, feeding stuffs, seeds, milk and dairy products, fats and oils, honey; materials and products of sugar, starch, spirits, beer, and wine making; water, dust and smoke injurious to vegetation, wool, beeswax, lubricants, etc.

**New official Italian methods of analysis of fertilizers,** L. SICARD (*Ann. École Nat. Agr. Montpellier*, n. ser., 5 (1906), No. 4, pp. 300-323).—The methods adopted by the directors of the agricultural experiment stations and laboratories of Italy in convention held in Rome in July, 1904, are described and critically discussed and compared with other methods for the same purposes. These include general methods of determining moisture, nitrogen, total phosphoric acid, potash, and iron and aluminum oxids, and methods of analysis of special fertilizers, such as superphosphates, aluminum phosphate, Thomas slag, ammonium sulphate, sodium nitrate, and farm manure.

**A further note on the determination of phosphoric acid by the citrate method,** V. SCHENKE (*Landw. Vers. Stat.*, 64 (1906), No. 1, pp. 87-91; *abs. in Chem. Centralbl.*, 1906, I, No. 19, p. 1573).—This is a reply to criticisms of the author's method by F. Mach (*E. S. R.*, 17, p. 731), in which further analytical data in substantiation of the accuracy of the method are reported.

**A method of detection and determination of small quantities of iron,** A. MOUNEYRAT (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 19, pp. 1049-1051).—A colorimetric method based upon the green coloration produced when hydrogen sulphid is passed through an alkaline solution of iron is described. It is claimed that the method is applicable to solutions containing from 1 part of iron to 1,000 parts of solution to 1 part to 100,000, and is more sensitive than the sulphocyanid method, being especially applicable in biological investigations.

**Tables for use in nitrogen and protein determinations,** F. E. HEPNER (*Wyoming Sta. Rpt.* 1905, pp. 61-71).

**The determination of nitrogen in milk,** M. POPP (*Milchw. Zentbl.*, 2 (1906), No. 6, pp. 263-268).—This report of experiments concludes with the following outline for determining nitrogen in milk: Into a short-necked digestion flask are put 10 gm. of milk (measured with a pipette), 25 cc. of pure concentrated sulphuric acid, 1 to 2 gm. of mercury, and some sharp-cornered pieces of glass. After heating gently for 10 minutes, 10 gm. of potassium sulphate is added and the mixture boiled for 30 minutes. After cooling and transferring to the distillation flask, 5 gm. of zinc dust is added and also the necessary sodium hydroxid when the distillation and determination are made in the usual way.

**The laboratory book of dairy analysis,** H. D. RICHMOND (*London: C. Griffin & Co., Ltd.*, 1905, pp. VIII+90).—This handbook on the composition and analysis of milk is intended for both the dairy manager and the trained chemist.

**New rapid method for the determination of fat in milk without the use of acid,** N. GERBER (*Rev. Gén. Lait*, 5 (1906), No. 14, pp. 318-321).—In this method, designated the salt method, the same apparatus is used as in the Gerber acid method, but the casein is dissolved by means of an alkaline solution, the exact composition of which is at present secret. Comparative determinations by the salt and acid methods are reported. They show very close agreement.

**The salt method,** M. SIEGFELD (*Molk. Ztg.*, 20 (1906), No. 14, pp. 371-373).—The salt mixture used in dissolving the casein in this new Gerber method is said to consist of sodium chlorid, sodium hydroxid, Rochelle salt, and a small quantity of coloring matter.

A solution is made by dissolving 230 gm. of this mixture in 1 liter of water. Eleven cc. of this solution, 10 cc. of milk, and 0.6 cc. of isobutylalcohol are mixed in the acid butyrometer, which is then placed in a water bath at 45° C. for 3 minutes and then centrifuged for 3 minutes. The reported results by the salt method are essentially the same as those by the acid method. The salt method is said to be uninfluenced by the presence of formalin or potassium bichromate in the milk.

**On the importance of determining the freezing point in milk analysis,** A. A. BONNEMA (*Pharm. Weekbl.*, 43 (1906), No. 18; *abs. in Rev. Gén. Lait*, 5 (1906), No. 15, pp. 346, 347).—The average freezing point of fresh cows' milk was found to be -0.555° C., which was increased as much as 0.02° by allowing the milk to stand for several hours or by boiling. Lactic fermentation lowered the freezing point. The importance of cryoscopy in detecting adulteration of milk is discussed.

**The detection of cocoanut oil in butter,** A. W. THORP (*Analyst*, 31 (1906), No. 363, pp. 173-175).—The author determines the Reichert-Wollny number in the usual way, then adds 110 cc. of water to the flask, and distills off a second 110 cc. and titrates this with tenth normal sodium hydroxid. The insoluble volatile acids are then dissolved in 100 cc. of 90 per cent alcohol slightly warmed and this is also titrated with the tenth normal soda solution.

The number of cubic centimeters of the tenth normal soda solution required in the 3 determinations were respectively 29.2, 3.1, and 7.6 for normal butter and 8, 4, and 34 for cocoanut oil. The addition of 10 per cent of cocoanut oil to butter increased the third determination to 10.2 and the addition of 90 per cent to 29.1. In no instance did the alcoholic solution show a higher number than 8.4 for pure butter.

**Plant lecithin; a preliminary communication,** E. WINTERSTEIN and O. HIRSTAND (*Ztschr. Physiol. Chem.*, 47 (1906), No. 4-6, pp. 496-498).—From their studies of the lecithin of cereals, lupines, and grasses, the authors are of the opinion that the name lecithin should no longer be applied to the organic bodies containing phosphorus, which occur in plants and are soluble in ether and alcohol, but that they should be termed phosphatides as has been suggested for similar products of animal origin.

**Experiments on amino acids, polypeptids, and proteids,** E. FISCHER (*Ber. Deut. Chem. Gesell.*, 39 (1906), pp. 530-610).—The cleavage of proteids yields, in addition to ammonia, albumoses, peptones, and finally amino acids. Albumoses and peptones are complex bodies but the acids are comparatively simple and the study of the chemical structure of proteids has been approached through this group.

The investigations have included synthesis and other studies of such acids, and several new and important methods of working with them and other products of proteid hydrolysis have been evolved. The general purpose of the author's work at present is to unite two or more amino acids to form a complex molecule and in this he has been successful and about 70 such bodies have been produced by his methods. The name polypeptids is proposed for these compounds, which are designated dipeptids, tripeptids, etc., according to the number of acid radicals entering into their structure. A tabular list of polypeptids is given. As a class polypeptids exhibit many

characteristics of proteids and in general it may be said that the author at present believes that albumins are polypeptids as regards structure.

**The identification of sugar in mace and in cinnamon**, E. SPAETH (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 11 (1906), No. 8, pp. 447-450).—A controversial article in which the author again states that sugar is a normal constituent of mace and cinnamon and summarizes data regarding its occurrence and estimation.

**A new method of estimating organic phosphoric acid in flour and flour products**, C. ARRAGON (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 11 (1906), No. 9, pp. 520, 521).—The proposed method consists essentially in extracting organic phosphorus with alcohol, igniting the residue obtained after evaporation, and determining the phosphorus as magnesium pyrophosphate.

**The detection of sawdust in flour and bread**, P. PAGANINI (*Gior. Farm. e Chim.*, 54 (1905), pp. 5-11; *abs. in Ztschr. Untersuch. Nahr. u. Genussmtl.*, 11 (1906), No. 9, p. 530).—The method of detecting sawdust depends upon the fact that wood when treated with paraphenyldiamin and acetic acid gives an orange-red color. Neither wheat flour nor corn meal gave such reaction.

**The brown deposit found on aluminium vessels in which water has been boiled**, C. FORMENTI (*Chem. Ztg.*, 29 (1905), No. 55, p. 746; *abs. in Hyg. Rundschau*, 16 (1906), No. 10, p. 557).—The brown deposit, the author states, is graphite-silicic acid, and is harmless.

## METEOROLOGY—WATER.

**Report of the meteorological council** (*Rpt. Met. Council* [Gt. Brit.], 1905, pp. 227, pls. 2, fig. 1, map 1).—This consists as usual of administrative reports regarding organization and operations (during the year ended March 31, 1905) in marine meteorology, forecasts and storm warnings, climatology, publication, and miscellaneous subjects, with appendixes relating to conspicuous meteorological occurrences in 1904, operations of the office in the 50 years since 1854, lists of logs and other documents received during the year, reports on inspections of meteorological stations, accessions to the library, list of persons and institutions to whom publications are sent, distribution of instruments, and financial statement.

The methods of distribution and the accuracy of weather forecasts are discussed, and it is shown that during the year 1904-5 57 per cent of the forecasts were completely successful, 31 per cent partially successful. The averages for 1895 to 1904 are 55.5 per cent completely successful, 28.2 per cent partially successful. The percentage of successful storm warnings in 1904 was 89.8.

**The work of the station of agricultural climatology of Juvisy during 1905**, C. FLAMMARION (*Bul. Mens. Off. Renseig. Agr.* [Paris], 5 (1906), No. 4, pp. 433-455, figs. 6).—A record is given of observations on atmospheric pressure, temperature of the air, soil, and underground water, relative humidity, rainfall, sunshine, and radiation, in continuation of those of previous years (E. S. R., 17, p. 440). Studies of the effect of different rays on plants and animals were also made as in previous years. Inconclusive studies of the influence of the moon on the germination and growth of various crops which have been noted elsewhere (E. S. R., 17, p. 532) are recorded.

The general course of the temperature of the air and of the soil at depths of 0.25, 0.5, 0.75, 1, and 1.5 meters was analogous throughout the year. During October, November, December, January, and February there was a series of rising temperatures which increased with the depth in the soil; in May, June, July, and August a series of falling temperatures which decreased with the depth. The temperature curves thus crossed in spring and again in autumn. The mean temperature of the water in wells about 14 meters deep was 11.3° C., 1.6° higher than that of the air, and the annual variation in temperature was 1.4° C.

**Meteorological records for 1904** (*New York State Sta. Rpt.* 1904, pp. 435-441).—Tables are given which show the average monthly precipitation since 1882; average

monthly temperature since 1882; tridaily readings of the standard air thermometer during each month of 1904; a monthly summary of maximum, minimum, and standard thermometer readings; and daily readings of maximum and minimum thermometers at 5 p. m. for each month of the year.

**Meteorological summary**, C. B. RIDGAWAY (*Wyoming Sta. Rpt. 1905*, pp. 76, 77).—A summary of observations at Laramie, Wyo., on temperature, atmospheric pressure, precipitation, evaporation, and direction and velocity of the wind during the year 1904. The mean temperature for the year was 41.9° F., the highest 83, July 12 and 15, the lowest -16, January 28; the mean barometric pressure was 23.024 in.; the total precipitation was 9.58 in., the mean for the past 10 years being 9.8 in.; the evaporation from May 7 to September 15 was 1.866 ft.

**The climate of Naples during the meteorological year 1903-4**, E. ANNIBALE (*Bol. Soc. Nat. Napoli*, 1. ser., 19 (1905), pp. 65-96).—Observations on atmospheric pressure, temperature, humidity, precipitation, direction of the wind, cloudiness, and storms are summarized and discussed.

**The rainfall régime and crops in Russia**, H. SAGNIER and E. TISSERAND (*Bul. Soc. Nat. Agr. France*, 66 (1906), No. 1, pp. 32-38).—Statements by A. Yermoloff regarding the dependence of crops, particularly wheat, upon the amount and distribution of spring rains, especially in central Russia, and the failure of crops in seasons of deficient or badly distributed rainfall, are reported and commented upon.

**Weather forecasting** (*Abstr. in Rev. Gén. Sci.*, 17 (1906), No. 8, pp. 350, 351).—A report by Durand-Gréville to the Belgian Astronomical Society on laws of storm movements in relation to weather forecasting is briefly reviewed, and a plea is made for a better system of weather forecasting in France.

**Protection of crops against hail in 1905 by means of cannon and bombs**, H. DUFOUR (*Chron. Agr. Vaud*, 19 (1906), No. 7, pp. 198-207).—The results of the campaign of 1905 are briefly summarized and the present status and possibilities of this method of protection are discussed.

**On the construction of isobaric charts for high levels in the earth's atmosphere and their dynamic significance**, J. W. SANDSTRÖM (*Trans. Amer. Phil. Soc.*, 21 (1906), No. 2, pp. 31-95, pl. 1, figs. 15).—It is shown how such charts can be constructed from meteorological observations obtained by means of kites and balloons in the free air, and the connection of the charts with the dynamics of the atmosphere is discussed. "It is to be expected that upon such maps we may easily and naturally present our observations and experience as to atmospheric movements and, therefore, it would seem to promise good results if the daily weather predictions could be based upon such maps."

**The gases of the atmosphere**, W. RAMSAY (*New York and London: The Macmillan Co.*, 1905, 3. ed.; rev. in *Chem. News*, 93 (1906), No. 2422, p. 199).—The principal new feature of this edition is a chapter on radio-activity and radio-active gases.

**Water and its use for industrial and technical purposes**, E. LEHER (*Das Wasser und seine Verwendung in Industrie und Gewerbe*. Leipzig: G. J. Göschen, 1905, pp. 124, figs. 15).—A concise treatise on the occurrence, physical and chemical properties, and testing of water, the technology of water for potable purposes, steam boilers, and special technical processes, water storage, and the disposal of sewage.

**The culture of anaerobic micro-organisms as applied to water analysis**, A. GUILLEMARD (*Ann. Inst. Pasteur*, 20 (1906), No. 2, pp. 155-160, fig. 1).—It is claimed in this article that present methods of bacteriological examination of water are defective in that account is taken only of the number of organisms which develop in the presence of air and that the probably equally important anaerobic organisms are not taken into consideration. A method for studying the relation between aerobic and anaerobic organisms in water is described, especially the apparatus and method to be used in the culture of anaerobic organisms in an atmosphere of hydrogen.

**The use of copper sulphate in water filtration**, H. W. CLARK and S. DEM.

GAGE (*Jour. Infect. Diseases*, 1906, Feb., Sup. 2, pp. 172-174).—Investigations are briefly reported which indicate that the use of copper sulphate as a preliminary treatment in the purification of sewage results in a lowering of the efficiency of subsequent filtration and bacterial purification of the filter bed.

**On the bactericidal action of copper**, H. W. CLARK and S. DEM. GAGE (*Jour. Infect. Diseases*, 1906, Feb., Sup. 2, pp. 175-204).—An account is here given of a series of experiments in which waters were treated with definite amounts of copper or copper sulphate or placed in contact with metallic copper and allowed to absorb an unknown amount of copper. The efficiency of the treatment was measured by its effect on the total number of bacteria and on the numbers of *Bacillus coli* and *B. typhosus* in the water.

The conclusion is reached that the treatment of water with copper sulphate or by storing in copper vessels has little practical value because it is not absolutely effective and is therefore dangerous in the hands of the general user. It was found in some cases that in order to insure the complete destruction of *B. coli* and *B. typhosus* it was necessary to use copper sulphate at the rate of 1 part to 1,000 of water, in which case the water was of a strongly astringent taste and would be repugnant to the user. Allowing water to stand in copper vessels for short periods was occasionally effective in removing *B. coli* and *B. typhosus*. In other cases, however, the very dilute solutions of copper sulphate or colloidal copper absorbed from contact with clean metallic copper appeared to have a decidedly invigorating effect on bacterial activity.

**The resistance to decomposition of certain organic matters in sewage**, H. W. CLARK (*Jour. Infect. Diseases*, 1906, Feb., Sup. 2, pp. 136-138).—It is shown in this article that a certain small percentage of exceedingly stable carbonaceous and nitrogenous matter accumulates year after year in filters used for ordinary domestic sewage and seriously impairs their efficiency. This material was found to resist nitrification and is believed to be of a carbonaceous rather than nitrogenous nature.

**Biological purification of sewage waters**, RICHE (*Ann. Chim. Analyt.*, 11 (1906), Nos. 1, pp. 16-19; 2, pp. 64-69).—The importance of biological processes as compared with chemical methods is discussed and various methods in which biological processes play a prominent part are considered, especially from the standpoint of disposal of Paris sewage. These include irrigation, and filter bed, septic tank, the Candy (intermittent sprinkling and carbolorrite) method of treatment, and others.

A consideration of the difficulties in the way of disposing of the Paris sewage by means of irrigation leads to the conclusion that the only solution of the problem appears to be a combination of bacterial purification and irrigation.

**Recent views of the sewage disposal problem** (*Engin. Rec.*, 53 (1906), No. 4, pp. 87, 88).—This is a brief editorial review of the recent rapid progress in this field, which is ascribed largely to progress in adopting better methods of sewage analysis, which yield fairly comparable results.

It is stated that "the old idea that sewage farming is the best method of disposal was exploded long ago, and the sewage farms still in service are not kept in operation because they afford the most economical method of treatment, as a rule. The rise of intermittent filtration has similarly reached its culmination. It is acknowledged to be the most perfect method of treatment when all conditions are favorable, but it is now known that it is much more expensive than was formerly anticipated, and the character of the effluent which it furnishes is often unnecessarily good for discharge into the body of water receiving the purified sewage. . . .

"Under these circumstances specialists in sewage treatment have been working to ascertain just what methods are best for securing different degrees of purification from the partial clarification resulting from simple sedimentation to the extreme

degree of purification attained with the best intermittent filters under the best operating conditions. . . .

"Along with this recognition of the varying requirements of sewage treatment are many new suggestions concerning the methods to be followed. The most interesting of these to the engineer who has not been following the development of the subject, is the closer connection which is gradually appearing between the principles of water purification and sewage treatment."

**Present practice in sewage disposal** (*Engin. Rec.*, 53 (1906), No. 4, pp. 97, 98).—This is a summary of a paper presented by G. W. Fuller at a recent meeting of the New Jersey Sanitary Association.

The paper emphasizes the desirability of preparatory treatment with raw sewage to remove the sludge, combinations of methods of purification, and treatment of the effluents with copper sulphate or other germicides, and describes comparative tests which have been made by the city of Columbus, Ohio, of various methods of sewage disposal. The preparatory treatment found most effective in these trials was afforded by septic tanks holding an average flow of about 8 hours, followed by the use of sprinkling filters operating at an average rate of 2,000,000 gal. per acre daily.

**The collection and preservation of samples of sewage for analysis**, S. DEM. GAGE and G. O. ADAMS (*Jour. Infect. Diseases*, 1906, Feb., Sup. 2, pp. 139-148).—Chloroform in amounts of 10 to 25 cc. to each gallon bottle is stated to be a good preservative for samples of sewage which are to be kept for some time before analysis.

### SOILS—FERTILIZERS.

**Some new properties of soils**, J. KONIG, J. HASENBAUMER, and E. COPPENRATH (*Landw. Vers. Stat.*, 63 (1906), No. 5-6, pp. 471-478).—This article discusses briefly the effect of steam on soils and the catalytic power and osmotic pressure of soils.

It is shown that by heating 250 gm. of a soil with 3 to 4 liters of water for 3 hours under a pressure of 4 atmospheres the solubility of the mineral constituents was increased to a considerable extent. Similar treatment acts like mercuric chlorid, chloroform, etc., in reducing the oxidizing or catalytic power of soils, which is ascribed to the action of oxydases (catalase) as well as bacteria. A device consisting of a Chamberland-Pasteur filter coated with gelatin rendered insoluble by the action of formaldehyde fumes for study of the osmotic power of soils is described, but no experiments with it are reported.

**A study of rock decomposition under the action of water**, A. S. CUSHMAN (*Chem. News*, 93 (1906), No. 2410, pp. 50-53).—This is a discussion of this subject based largely upon investigations which have already been noted (*E. S. R.*, 17, p. 301).

Data are presented to show that electrical endosmosis offers an efficient means of separating not only water but also acids or alkalis from slimy, colloidal, and otherwise unfilterable mixtures such as are obtained with very fine rock powders. It is shown that by successive grindings and treatment with an electric current the potash can be removed from orthoclase and other minerals containing potash.

In the experiments reported "definite weights of the rock powders were slimed with a measured quantity of water, and the slime placed inside an ordinary unglazed porcelain cup such as is used for certain common types of bell batteries. An ordinary arc-light carbon was then inserted and the porcelain cup set down inside a glass cylindrical vessel containing distilled water to the depth of 2 or 3 cm. Another carbon electrode was then inserted in the outside compartment. The cell was then connected with a direct current of about 110 volts, the inner or slime chamber being in connection with the positive pole.

"Under the action of electrical endosmosis all the liquid from the anode or slime chamber passed into the cathode chamber, while at the same time, owing to electrolysis, the free alkali passed out in a condition in which it could be easily titrated or otherwise estimated. In the course of a few hours the slime had been transformed

into a hard, comparatively dry cake, while the free alkali had been partially removed. The alkaline liquor in the cathode chamber was then poured out into a beaker and titrated with tenth-normal acid. After resliming the material in the anode chamber with the proper quantity of water, the apparatus was started again. With the conditions under which we were working it was found that about one hour sufficed for each run."

**The absorption of potassium by soils**, O. SCHREINER and G. H. FAILYER (*Abstr. in Science*, n. ser., 23 (1906), No. 583, p. 324).—This is an abstract of a paper presented at the New Orleans meeting of the American Association for the Advancement of Science.

The absorption of potash by soils was studied by the same methods used in case of phosphates and an equation representing the absorption is worked out, which is as follows:  $\frac{dy}{dv} = K(A - y)$ , in which  $K$  is a constant,  $A$  the maximum amount of potassium the soil can absorb under the conditions of the experiment, and  $y$  the amount it has absorbed when a volume  $v$  of potassium solution has passed through the soil. "The removal by water of the absorbed potassium is rapid at first, but the concentration of the percolates soon reaches a constant value, although only a fractional amount of the absorbed potassium has been removed. As far as the observations have been made the solutions obtained by percolating a solution of potassium chlorid through the soil have always been acid."

**The absorption of phosphate by soils**, O. SCHREINER and G. H. FAILYER (*Abstr. in Science*, n. ser., 23 (1906), No. 583, pp. 324, 325).—This is an abstract of a paper presented at the New Orleans meeting of the American Association for the Advancement of Science. The subject was studied by percolating different phosphate solutions through soils of several types in an apparatus especially designed for the purpose and analyzing separate fractions of the solution which passed through. The absorption phenomena are represented graphically, and a differential equation, which is said to quite accurately describe them, is given. It was found that the absorptive capacity for phosphates varied greatly in different soils, being as a rule most pronounced in the clays and loams and less so in the sandy soils.

"The solubility of the phosphate originally present in the soils was also determined by percolating water through the untreated soils in the above-mentioned apparatus. It was found that the concentration of the separate fractions of percolate was practically a constant for each of the soils studied. If this concentration is reduced through any cause, such as the absorption by plants or influx of rain water, the original concentration will be again restored by more of the phosphate of the soil entering into solution. If, on the other hand, the solution is somewhat stronger than the natural concentration for that soil through any cause whatever, such as the application of a soluble phosphate, the concentration is reduced by absorption to the original strength. . . .

"This constancy in the strength of the soil solution, so far as phosphate is concerned, is further shown by the removal by water of the absorbed phosphate, which has been similarly investigated. It was found that the concentration of the separate percolates decreases rapidly until the concentration is reduced approximately to that of the original soil solution. This concentration of phosphate is then maintained with much persistence, although only a fractional amount of the absorbed phosphate has been removed, thus indicating that while the absorbed phosphate is apparently rendered insoluble, it is, nevertheless, slowly but constantly going into the soil moisture and is, therefore, available to plants."

**The absorption of phosphates and potassium by soils**, O. SCHREINER and G. H. FAILYER (*U. S. Dept. Agr., Bur. Soils Bul. 32*, pp. 39, figs. 6).—A briefer account of the investigations reported in detail in this bulletin has already been noted (see above).

**The solubility of phosphoric acid in sugar-beet soils, J. STOKLASA** (*Bt. Zuckerrubenbau*, 13 (1906), Nos. 1, pp. 1-9; 2, pp. 17-25, pls. 2; *abs. in Chem. Ztg.*, 30 (1906), No. 16, *Repert.* No. 4, pp. 55, 56).—The importance of carbon dioxide produced by micro-organisms in the soil and given off by plant roots as a means of rendering the soil phosphates assimilable is discussed.

It is estimated that 1 gm. of a humus soil contains probably 20 to 30 million micro-organisms, which, with a 20 per cent water content and a temperature of 15° C., are capable of producing 50 to 60 mg. of carbon dioxide per day. The most rapid production of carbon dioxide occurs in the soil at the depth of 10 to 40 cm. and amounts during the growing period (150 days) to 112.5 metric centners per hectare (5,010.12 lbs. per acre).

The author's observations indicate that the fine roots and root hairs of sugar beets are capable of producing as much as 960 kg. of carbon dioxide per hectare in 60 days. The carbon dioxide dissolved in water exerts a direct solvent action on the phosphates of the soil.

**On the improvement of a soil relatively deficient in magnesia, T. NAKAMURA** (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1 (1905), No. 1, pp. 30-34).—In pot experiments with a soil containing 17 times as much lime as magnesia it was found that although there was sufficient magnesia for the growth of barley plants, the addition of magnesia was very beneficial. The most favorable ratio of lime to magnesia was 7:1, provided the magnesia was applied in the form of sulphate.

"Since the best ratio of lime to magnesia for the growth of cereals was found to be 1:1 when magnesia was applied in the form of magnesite, it would have required 333 gm. magnesite per pot in order to attain the above ratio. As the best result was, however, obtained when 78.72 gm. magnesium sulphate were applied per pot, we may conclude that the relative value or agronomical equivalent of magnesium sulphate to magnesite is here nearly 23:100."

**Meeting of the fertilizer section of the German Agricultural Society** (*Mit. Deut. Landw. Gesell.*, 21 (1906), No. 7, pp. 69-74).—Short accounts are given of the discussion of the following topics: The use of commercial fertilizers in Bavaria, preservation of barnyard manure and its most profitable use, and the influence of deficiency or excess of rainfall on the action of fertilizers.

Investigations by Pfeiffer at Breslau and Immendorff at Jena on the preservation of manures are summarized. The latter show that there is a considerable loss of nitrogen in the stall, and this is greater if the manure is allowed to lie for some time (say 7 days) under the feet of the animals than if it is removed daily. Contact with already fermenting manure apparently hastens the loss of nitrogen. The loss is greater both in the stall and in the heap in warm weather than in cold.

Kainit and superphosphate gypsum used at rates of 1.5 to 2 kg. per 1,000 kg. of live weight of animal were practically worthless. The use of sulphuric acid and superphosphate gypsum in amounts (3 kg. per 1,000 kg. live weight) giving a permanent acid reaction quite effectively prevented loss of nitrogen, but this is not practicable on account of excessive cost. The use of peat litter is the most effective means of preventing loss. In the experiments reported the loss of nitrogen was reduced to 7.3 per cent. The loss of nitrogen was less when the liquid manure was separated from the solid than when the two were mixed.

**The sale of sheep manure, F. DE BARRAU** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 11, pp. 341-343).—A brief note on local trade in this article and on its composition and fertilizing value. The following analysis is reported: Nitrogen (organic and ammoniacal) 1.36 per cent, phosphoric acid 0.26 per cent, potash 1.17 per cent, water 60.33 per cent. The manure is valued especially by viticulturists. Attention is called to the danger of impoverishing the farm by selling this material without returning an equal amount of fertilizing material in some other form.

**Fertilizers on cereal crops grown in rotation, C. E. THORNE** (*Ohio Sta. Circ. 54, pp. 15*).—This circular summarizes the results of 12 years' experiments on the station farm at Wooster, 11 years on the test farm at Strongsville, in northeastern Ohio, and 2 years each on the test farms at Germantown in southwestern Ohio and Carpenter in southeastern Ohio.

The crops grown at Wooster and Strongsville were a 5-year rotation of corn, oats, wheat, clover, and timothy; on the other farms a 3-year rotation of wheat and clover. The fertilizers used were phosphoric acid in form of acid phosphate alone and combined 2 by 2, and all 3 together with potash in form of potassium chlorid and nitrogen as nitrate of soda. Experiments at Wooster with barnyard manure untreated and treated with gypsum, floats, and acid phosphate are also briefly reported.

The results show that corn and oats responded profitably to moderate applications of phosphoric acid on the soils experimented with, which are believed to be typical of the soils of the State in general. The addition of potash to phosphoric acid in the fertilizer sometimes, but not always, gave a profitable increase in the yield of corn and oats.

The use of potassium seems to be especially indicated in regions where hay and straw, as well as grain, have been sold off the land for a considerable period, or where tobacco, cabbage, or other crops, in which the entire plant is taken off the farm, have been extensively grown.

"The complete fertilizer, containing nitrogen and potassium, as well as phosphorus, nearly always produced a larger total increase of corn and oats than any partial fertilizer; but when the nitrogen and potassium were purchased in commercial fertilizers their cost was usually greater than the additional gain, over that produced by phosphorus alone, was worth.

"The complete fertilizer invariably produced a larger increase in the wheat crop than that given by any partial fertilizer, and on the hard-run land at the main station, which has been exhaustively cropped with cereals for 60 to 75 years, the additional increase in the wheat and hay crops resulting from the use of the complete fertilizer more than offset its largely increased cost, leaving a larger net gain than that obtained from any partial fertilizer; but on land that had been resting in pasture for many years or on land in a high state of fertility the increase from the complete fertilizer has not yet been sufficient to justify its use, if the nitrogen and potassium must be purchased in commercial carriers; but in farm manure nitrogen and potassium may be secured practically without cost, and these experiments have shown that such manure may be made as effective a carrier of these elements of fertility as the most active forms in which they are found in commercial fertilizers." The barnyard manure treated with acid phosphate or floats was an especially effective fertilizer.

**Inoculation of leguminous plants** (*Jour. Bd. Agr. [London], 12 (1906), No. 11, pp. 641-659, figs. 3*).—This is an account of tests by 13 agricultural colleges and experiment stations in Great Britain of Hiltner's nitrugin and Moore's inoculating material distributed by the Board of Agriculture. The general plan of the experiments include laboratory tests with sterilized soil or sand, pot cultures in unsterilized soils from various sources, and tests in accord with actual agricultural or horticultural practice, including inoculation of areas of field soil of various sizes.

"As a result of all the reported experiments, it seems evident that the cultures used were not uniform; it is not possible, however, to determine the extent to which the failures are to be attributed to this cause. It seems, however, from the positive results recorded that not only are these cultures sometimes able to produce nodules on the roots of plants new to a neighborhood, but that even in cases where the leguminous crop had been grown in the previous year benefit may be derived from inoculation.

"It is quite evident that the subject of plant inoculation in this country has not yet passed the experimental stage, and more work is required before one can feel at all justified in recommending either method for adoption on a field scale; nevertheless, the positive results obtained may lead farmers to hope that in the future benefit may be derived, in some instances at least, from the treatment of the soil or the seed before sowing, with inoculating materials preparatory to growing leguminous crops."

**The fixation of atmospheric nitrogen** (*Engineering* [London], 81 (1906), No. 2090, pp. 89, 90; *Sci. Amer. Sup.*, 61 (1906), No. 1573, pp. 25205-25207).—This is a review of investigations on this subject, including in some detail the recent developments along this line in Norway and a list of references to the more important literature of the subject.

**Fixation of atmospheric nitrogen**, P. A. GUYE (*Electricien*, 1905, Dec. 30, Sup., p. 417; *abs. in Rev. Sci. [Paris]*, 5. ser., 5 (1906), No. 12, pp. 376, 377).—Investigations on this subject are briefly reviewed, and it is pointed out that the progress made toward the development of commercially successful methods must be based upon scientific investigations and theoretical considerations.

**The fixation of atmospheric nitrogen** (*Rev. Gen. Sci.*, 17 (1906), No. 6, p. 260).—It is stated that the method of producing expanded arcs used by Birkeland and Eyde was first described by Plucker in 1861.<sup>a</sup>

**On the utilization of atmospheric nitrogen**, W. LÖB (*Umschau*, 10 (1906), No. 14, pp. 265-271, figs. 7).—An illustrated account is given of the Birkeland and Eyde process as carried out at Notodden.

**The manufacture of nitric acid at Notodden**, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 10, pp. 296-299, figs. 4).—The plant and methods used at this place for the preparation of nitric acid from atmospheric nitrogen by the Birkeland and Eyde process are described.

**The factory at Notodden, Norway, for the manufacture of nitrate**, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 11, pp. 328-330, figs. 2).—Further descriptive details regarding the factory established at this point for the manufacture of nitrate from atmospheric nitrogen by the Birkeland and Eyde process.

**The electric furnace of Birkeland and Eyde**, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 9, pp. 265-268, figs. 3).—The principles of construction of this furnace are explained and statistics are given as to the extent to which it is being used in Norway in the preparation of nitrogen compounds from the air.

**Calcium cyanamid** (*Mark Lane Express*, 94 (1906), No. 3883, *Fert. and Feed.*, p. 11).—It is stated that the German Agricultural Society announces that it is now prepared to furnish this material, with 19 per cent nitrogen, in limited quantities for fertilizer tests at a cash price of about \$53.53 per ton, in bags 1.0 b

**Nitrogen and nitrogenous fertilizers**, P. G. WICKEN (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 3, pp. 252-256).—This article explains briefly the different forms in which nitrogen occurs and discusses the fertilizing value of the nitrogenous fertilizers available for use in West Australia, including nitrate of soda, nitrate of potash, ammonium sulphate, soot, blood manure, bone dust, tankage, guanos, urine and night soil, oil cake, wool waste, decomposed hair and lime from tanneries and fellmongeries, barnyard manure, and seaweed.

**Production of nitrate**, R. E. MANSFIELD (*Mo. Consular and Trade Rpts.* [U. S.], 1906, No. 305, p. 53).—The exports of nitrate from Chile to different countries during the year 1904 are given, the total being 740,869 tons, valued at \$52,847,132.

**The use of ammoniacal gas liquor as a fertilizer**, C. DUSSEY (*Ann. Agr. Suisse*, 6 (1905), No. 3, pp. 333-335; *Bul. Mens. Off. Renseign. Agr.* [Paris], 5 (1906), No. 2, pp. 183-185).—Experiments with a liquor obtained from the gas works of Morges containing from 0.37 to 0.45 per cent of nitrogen, mostly in form of ammonia, but also containing small amounts of sulphid, cyanid, sulphocyanid, etc., are reported.

<sup>a</sup> Ann. Phys. [Poggendorff], 113, p. 252.

The material was applied to grass lands in connection with superphosphate, 500 kg. per hectare (445 lbs. per acre), and potash salts, 300 kg. per hectare (267 lbs. per acre) at rates of 5,000 to 15,000 liters per hectare (about 3,300 to 9,900 gal. per acre) on March 20 and June 8, before and after the first cutting of grass. The smaller application produced very little increase in yield. The larger application produced sufficient increase in yield to pay the cost of transportation and distribution. The addition of sulphate of iron, 500 kg. per hectare (445 lbs. per acre) further increased the yield and completely destroyed mosses in the grass. The use of the gas liquor resulted in the disappearance of leguminous plants from the herbage, but favored the development of the graminæ. The first application of the liquor burned the grass more or less, but it promptly recovered from this injury.

The general conclusion reached was that farmers in the vicinity of gas works may use this material with advantage if they can secure it free of cost. It may be applied with advantage during the winter on grass lands or on uncultivated land either directly or in mixture with liquid manure. Since it contains only nitrogen, it should be supplemented with phosphatic, potassic, and calcareous fertilizers. If applied directly during the summer it may seriously injure plants, but it may be safely used in mixtures with soil or compost.

**Bone products,** J. C. McNALLY (*Mo. Consular and Trade Rpts.*, 1906, No. 305, p. 155).—A brief note is here given on the composition and fertilizing value of raw and degelatinized bone meal and precipitated bone phosphate. The use and value of the precipitated phosphate as a feeding stuff is also referred to.

**Phosphate rock production,** E. O. HOVEY (*Amer. Fert.*, 24 (1906), No. 3, p. 21).—Statements from advance reports of the U. S. Geological Survey are cited showing that the marketed production in 1905 probably exceeded 600,000 long tons as against 530,571 tons in 1904. There was a marked increase in production in Florida and Tennessee and a smaller increase in South Carolina. The average price of phosphate was higher in 1906 than in 1905 due to increased demand in Europe.

**Potash as a fertilizer,** P. G. WICKEN (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 5, pp. 422-424).—A concise summary is here given of the principal facts relating to this subject.

**Analyses of commercial fertilizers,** M. A. SCOVELL ET AL. (*Kentucky Sta. Bul.* 121, pp. 83-153).—Analyses and valuation of 421 samples of fertilizers inspected during the spring of 1905 are reported.

**Analyses of fertilizers,** C. A. GOESSMANN (*Massachusetts Sta. Bul.* 107, pp. 42).—This bulletin gives market values of fertilizing ingredients and reports analyses of licensed fertilizers collected in the general market and miscellaneous fertilizing materials sent to the station for examination, including wood ashes, lime ashes, cob ashes, cotton-seed meal, Peruvian guano, meat and bone, tankage, factory waste, kiln-dried pulverized sheep manure, sheep manure, soils, muck, and complete fertilizers.

**Analyses of fertilizers and insecticides,** C. A. GOESSMANN (*Massachusetts Sta. Bul.* 109, pp. 23).—This bulletin includes notes on the taking of samples for analysis, instructions to manufacturers and dealers in commercial fertilizers, a discussion of trade values of fertilizing materials for 1906, and analyses of miscellaneous fertilizing and insecticide materials.

The list includes wood ashes, cotton-hull ashes, lime ashes, refuse ashes, nitrate of soda, cotton-seed meal, new process linseed meal, dried blood, high grade sulphate of potash, carbonate of potash, muriate of potash, double manure salts, kainit, dissolved boneblack, superphosphate, dissolved bone, ground bone, tankage, dry ground fish, carbonate of lime, prepared lime, cotton waste, cotton-seed compost, rotted cotton waste, damaged cocoa, glue refuse, leather dust, bone soup, refuse from wool washings, factory refuse, muck, peat, mud from the decomposition of seaweed, granulated tobacco stems, Peruvian guano, pigeon manure, complete fertilizers, soils, Paris green, arsenate of lead, and other insecticides.

**Analyses of commercial fertilizers**, P. SCHWEITZER and R. M. BIRD (*Missouri Sta. Bul.* 66, pp. 8).—This bulletin contains a report of analyses of commercial fertilizers collected during the fall of 1904 and the spring of 1905, as well as a financial statement of the receipts and disbursements of the fertilizer control fund for the year ended December 31, 1904.

**Analyses of commercial fertilizers**, P. SCHWEITZER and R. M. BIRD (*Missouri Sta. Bul.* 70, pp. 11).—This bulletin reports analyses of commercial fertilizers collected during the fall of 1905, and gives a statement of receipts and disbursements of the fertilizer control fund for the year ended December 31, 1905.

**Commercial fertilizers**, W. W. MILLER and N. W. LORD (*Offic. Rpt. Sec. Ohio Bd. Agr. on Com. Fertls.*, 1905, pp. 100).—The results of inspection of fertilizers in Ohio during the year 1905 are given, with statements regarding the fertilizer control and the valuation of fertilizers, and the text of the State fertilizer law.

**Licensed commercial fertilizers, 1906**, F. W. WOHL and G. A. OLSON (*Wisconsin Sta. Bul.* 134, pp. 1-17, 24-26).—Analyses of 22 brands of fertilizers licensed for sale in Wisconsin during 1906 are reported, with a brief general discussion on the purchase, valuation, and use of commercial fertilizers, and the text of the State fertilizer law.

**Fertilizers in Japan** (*Bd. Trade Jour. [Gt. Brit.], 1906, Jan. 4; abs. in Jour. Soc. Chem. Indust.*, 25 (1906), No. 2, p. 84).—Statistics are given showing the extent and increase of use of fertilizers in Japan, especially of oil cakes.

The value of the fertilizers imported into Japan during the first 6 months of 1905 is reported to have been 12,976,352 yen (\$6,462,223 30). Of this amount 7,265,109 yen (\$3,618,024.28) was paid for oil cake, 638,217 yen (\$317,832.07) for ammonium sulphate, 1,179,304 yen (\$587,293.39) for calcium phosphate, and 636,997 yen (\$317,224.51) for sodium nitrate. The oil cake comes from China, one-third of the nitrate from the United States, and the remainder from Chile and various other countries, the calcium phosphate and ammonium sulphate from the United Kingdom. There are several chemical factories at Osaka which produce fertilizers, especially ammonium sulphate.

**Artificial fertilizers**, P. G. WICKEN (*Jour. Dept. Agr. West. Aust.*, 1? (1905), No. 1, pp. 7-18).—This article discusses especially the prices and value of the fertilizing materials available in West Australia, and gives formulas for fertilizer mixtures for various kinds of crops, with directions for their application. The draft of various crops on the fertilizer constituents of the soil is also explained.

## AGRICULTURAL BOTANY.

**Plant breeding**, L. H. BAILEY (*New York and London: The Macmillan Co.*, 1906, pp. XIV+483, figs. 43).—This is a fourth edition of the author's work on plant breeding, which first appeared in 1895 (E. S. R., 7, p. 562).

The most marked changes in this work are to be found in chapter IV, which has been wholly rewritten and which gives a résumé of the investigations of de Vries, Mendel, and others, and in chapter V, which gives accounts of current plant-breeding practice. This last chapter summarizes the work of Burbank and Keeney, and the investigations of the experiment stations and of this Department along this line. A chronological bibliography of references to such literature as English-speaking horticulturists would be most likely to find completes the volume. The bibliography embraces something over 100 pages and is brought down to 1905.

**On the correlation between calcium salts and the assimilation of nitrate nitrogen**, V. V. YERMAKOV (*Zhur. Opušn. Agron. (Russ. Jour. Expt. Landw.)*, 6 (1905), No. 4, pp. 403-431).—The formation of ammonia and oxalic acid when nitric acid acts on glucose suggested to the author the possibility of a similar reaction taking place in plants during the assimilation of nitrate nitrogen, whereby the ammonia

serves for the synthesis of albumin and the oxalic acid, precipitated by the calcium, remains without further influence. If this hypothesis were true, in the absence of calcium salts the oxalic acid formed would not be neutralized, and, being injurious to plants even in small quantities, would hinder the assimilation of the nitrate nitrogen.

To determine this subject the author carried out 3 series of experiments with leaves of grapes, *Paulownia imperialis*, and *Ailanthus glandulosa*. In these experiments the author used one side of the leaves of grapes and *Paulownia* and the leaflets on one side of the rachis of *Ailanthus*, the other portions remaining as a check. The nitrate nitrogen was determined by the Schultze-Tiemann method.

In the first series of experiments some of the leaves were placed for 24 hours in a 0.2 per cent solution of calcium nitrate and others in a 0.2 per cent solution of potassium nitrate. At the end of the experiments only traces of nitrate nitrogen were found in the leaves receiving the calcium solution, while the leaves placed in the potassium solution contained an appreciable quantity of nitrate nitrogen. This seems to indicate that in the leaves receiving calcium the nitrate was consumed by the plant.

In the second series of experiments the leaves were placed in a 0.2 per cent solution of potassium nitrate and were then cut in halves, some of which were used as controls while others were placed in various solutions. The results show that in the leaves which had received calcium salts the nitrate disappeared, being assimilated, while where no calcium salt was present the nitrate remained unaffected. The author concludes from this that calcium is indispensable for the assimilation of nitrate nitrogen.—P. FIREMAN.

**The morphology and biology of nitrogen-assimilating organisms, L. LUTZ** (*Les microorganismes fixateurs d'azote. Paris: J. Lechevalier, 1904, pp. 187, figs. 19; abs. in Centbl. Bakt [etc.], 2. Abt., 15 (1905), No. 15-16, pp. 477, 478*).—The author gives a critical review of the literature relating to nitrogen assimilation by bacteria and other micro-organisms and practically gives a summary of the present status of knowledge on the morphology and biology of nitrogen-assimilating organisms.

After a historical résumé, the author gives an account of the attempts to cultivate the nitrogen-fixing organisms, particularly the experiments of Winogradski and Beijerinck, and of the cultures known as Alinit. The general conditions for fixation of nitrogen in the soil and factors limiting it are described, after which especial attention is given the morphology and physiology of the tubercles on the roots of the Leguminosæ and of the organisms which they contain. The literature on the culture of these organisms is reviewed at considerable length, and suggestions are given for the growth of the bacteria in nitrogen-containing and nitrogen-free media. The biological forms and physiological characteristics of the organisms are described and the various factors controlling nitrogen assimilation are reviewed. Accounts are given of various attempts in the utilization of the bacteria by applying them to practical use in the field, particularly on the use of pure cultures.

In addition to the Leguminosæ the author shows that tubercles of a similar nature occur on the roots of alders, *Eleagnus*, *Podocarpus*, *Myrica*, *Datisca*, etc.

A chapter is devoted to the fixation of free atmospheric nitrogen through symbiosis between algae and bacteria by mosses, etc.

An extended bibliography of literature completes the volume, about 500 titles being cited.

**Effect of differences in solar radiations on the transfer of albuminoids in wheat, J. DUMONT** (*Compt. Rend. Acad. Sci. [Paris], 141 (1905), No. 18, pp. 686-688*).—It having been claimed that light is necessary for the formation of albuminoids in plants and that the more refrangible rays are most active in this respect, the author investigated the subject and reports experiments carried on during 2 different

seasons to test the effect of blue, black, red, and green colored screens on the production of grain and chaff of wheat.

In 1904 the wheat grown under the black screen was richest in nitrogen, followed by the specimens grown under green, blue, and red screens. In 1905 the experiments were repeated, and in this case the highest amount of nitrogen was found in the plants grown under the green screens, followed by those under the black, blue, and red.

Incidentally the effect of these different colored screens on germination was tested, and out of 100 grains selected, 92 germinated in the check, 94 under the black, 97 under the red, and 99 under the blue and green screens.

**Anatomical and physiological changes produced in tropical plants by change of environment.** D. BOIS and I. GALLAUD (*Compt. Rend. Acad. Sci. [Paris]*, 141 (1905), No. 24, pp. 1033-1035).—Attention is called to the marked physiological and anatomical changes which take place in various economic tropical plants when taken from one region to another, and the failure to secure the successful economic introduction of many plants, such as rubber, fiber plants, etc., is attributed to these changes.

**Wound stimuli, parasitism, and gum flow of the Amygdalaceæ.** M. W. BEIJERINCK and A. RANTÉ (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 12, pp. 366-375).—On account of the frequent occurrence of gum flow associated with certain diseases of species of *Prunus*, the authors have investigated the theories of the effect of wound stimuli to gum flow and the relation of parasites to wound stimuli.

The principal experiments were made with young shoots of the peach and of a reputed hybrid between the peach and almond. The effect of wounding the cambium in both young and old twigs is shown and comparisons are made with the stimulus caused by poisons, heat, etc. The influence of species of fungi in inducing wound stimuli is described, and gum flow is reported as associated with a considerable number of species. In conclusion comparisons are drawn between this form of gum secretion and the resins and gums produced by other plants.

**Some experiments in the control of color in plants.** H. KRAEMER (*Abs. in Science*, n. ser., 23 (1906), No. 585, pp. 423, 424).—In a previous publication (*E. S. R.*, 16, p. 540) the author shows that the unorganized or cell-sap color substances in plants readily react with various chemicals, producing in many instances marked changes in color. It was found that the majority of plant-color substances turned green when under the influence of calcium hydrate, deep red with organic acids, rich purple with potassium and aluminum sulphate, and blue with iron sulphate.

In 1904 the author carried on a series of experiments in this Department for the purpose of determining the effects of certain chemicals on the color principles of plants, the material studied being carnations, roses, and pansies, which were grown in the presence of a large number of chemicals. The results published are considered only preliminary, but it was found that in the case of La France roses the petals became of a uniform pink color when the plants were supplied with iron citrate and citric acid. Maroon roses became dark red when the plants were supplied with phosphoric acid, iron and ammonium sulphate, or sulphuric acid. The maroon roses when treated with sulphuric acid were found to take on a crimson color and they also tended to produce single flowers.

**Some factors concerned in color production in a species of *Fusarium*.** J. B. POLLOCK (*Abs. in Science*, n. ser., 23 (1906), No. 585, pp. 422, 423).—A series of experiments was carried on with species of *Fusarium* obtained from the cut ends of corn stubble.

One of the characteristics of the fungus is the bright salmon-pink color which develops on many artificial media under proper conditions. Among the conditions necessary for its development are direct sunlight, in the absence of which only a pale cream color is produced, generally without a tinge of red. Moisture is also an impor-

tant factor in the development of color, and various media were found to influence the color produced by the fungus in a marked degree.

**The induction of new species.** D. T. MACDOUGAL (*Abs. in Science, n. ser., 23* (1906), No. 585, p. 422).—The effect of some chemical agents on the development of new species is briefly described in an account of experiments in which the ovaries of *Raimannia* were stimulated immediately previous to fertilization.

Among the seeds secured were a number which produced plants differing from the normal or typical species, and the series of experiments seems to demonstrate that factors external to the protoplast may exert a profound influence upon the hereditary characters, developing qualities not hitherto exhibited in the parent plants.

## FIELD CROPS.

**Report of the agriculturist.** B. C. BUFFUM (*Colorado Sta. Rpt. 1901, pp. 20-31, pl. 1*).—A brief report of the work of the agriculturist during the season of 1901 is given. Several varieties of wheat grown for a number of years at altitudes of 7,000 ft. showed a remarkable deterioration when planted at the station. In a field experiment with potatoes, untreated selected clean seed gave the largest yield. The shrinkage of 8 lots of potatoes during 4½ months ranged from 5.2 to 8.5 per cent. Notes are given on a number of varieties of macaroni wheats tested in 1901.

The results obtained with Hanna barley indicated that the variety is well adapted to Colorado conditions. Black oats from Colorado seed gave 71 bu. per acre, North Finnish 60.5 bu., and Silesian 52.4 bu. Three acres of Russian spelt, sown at the rate of 100 lbs. per acre, yielded 181 bu., machine measure. The crop weighed 5,386 lbs., or about 30 lbs. per bushel.

**A report of the cooperative grass and forage plants experiments with the U. S. Department of Agriculture at the Colorado Agricultural Experiment Station in 1901.** A. H. DANIELSON (*Colorado Sta. Rpt. 1901, pp. 32-38, pls. 4, dgm. 1*).—The grass garden of the station is described and the species making a good growth, a moderate growth, little growth, or dying out after coming up, and those not germinating are listed and the more important and successful ones briefly noted. The grasses and forage plants under field culture are also briefly discussed.

**Succotash as a soiling crop.** R. S. SHAW (*Michigan Sta. Bul. 235, pp. 113-127, figs. 4*).—The advantages and disadvantages of several crop mixtures grown for forage from 1903 to 1904, inclusive, are pointed out and notes on their culture and uses are given.

On May 8, 1903, a mixture of 1 pk. of corn, 1 pk. of peas, 1 pk. of oats, and 6 qts. of barley was drilled at the rate of 2½ bu. per acre. The cutting and feeding of this crop to pigs was begun June 24 and lasted 12 days. The yield was at the rate of 22,887 lbs. of green crop per acre. Owing to abundant rainfall, the growth was exceedingly dense and tall. The objection to this mixture was that it did not contain plants making a second growth after cutting.

In 1904 corn, peas, oats, rape, and millet were sown May 7 on two different plats. Pigs were turned in one plat on June 20 and kept there for 32 days. The second growth of rape and millet in this mixture was good.

In 1905 corn, oats, peas, rape, and clover were sown May 1 on one plat and May 20 on another. Floods interfered with the crop, but the data secured from the early sowing showed a yield of green forage of 12.16 tons per acre. Samples taken from 4 representative areas each 2 ft. square showed that these 16 sq. ft. had produced the following number of plants: Oats, 61; peas, 68; rape, 55, and corn 22, their weights being 10.6, 4.2, 2.75, and 0.5 lbs., respectively. The second sowing yielded at the rate of 12.62 tons of green forage per acre and the 4 representative areas, including 16 sq. ft., in this case contained the following number of plants: Corn, 74; peas, 82; oats, 43, and rape 10, the respective weights being 6.9, 1.7, 4.3, and 0.3 lbs. The cutting of this sowing began July 22 and was completed August 11. The composition of samples taken in 1904 and 1905 is recorded.

[Experiments at the agricultural experiment station at Vienna, 1905], O. REITMAIR (*Zschr. Landw. Versuchsw. Oesterr.*, 9 (1906), No. 3, pp. 148-179).—The work of the department of agronomy is reviewed and the results secured are briefly reported.

The average results of several fertilizer tests with potatoes, sugar beets, winter rye, and winter wheat show that of the total increase in yield secured from the complete application the following percentages were due to the use of nitrate of soda: Potatoes 48.7, sugar beets 38.2, winter rye 57.5, and winter wheat 40 per cent. The hoed crops received 200 kg. of nitrate per hectare and the cereals 150 kg. These comparatively small applications are regarded in general as the most profitable for the soils under test.

Potash was applied in the form of kainit and potash salt in quantities furnishing 100 kg. of potash per hectare, and the effect of this single application observed for 3 years. The first year the increase in the different crops due to potash was medium and regular, but where kainit was applied to oats no increase was secured. The second year the effect of potash on all crops excepting clover was weak, being weakest with oats. The third year the residual effect was still quite noticeable with clover, where the potash salt showed a better growth than the kainit, while the year before the kainit produced the better crop. The potash requirements of barley did not seem greater than those of other cereals.

Fertilizer experiments on meadows and inoculation experiments with different leguminous plants, together with other work of the station are also reviewed.

**Fertilizer experiments on meadows**, A. GRETE (*Landw. Jahrb. Schweiz*, 20 (1906), No. 2, pp. 117-148).—The results of cooperative experiments carried on from 1898 to 1900, inclusive, are reported. The plots, each containing 100 square meters, were given various combinations of phosphoric acid, potash, nitrogen, and lime at the rate of 0.8, 1, 0.45, and 2 kg. per plot, respectively. Lime was applied only in 1898.

It was found that the soil was very much in need of phosphoric acid while its potash requirement was small, the yields with phosphoric acid alone being almost as large as where the 2 elements were given together. Nitrogen gave a small increase in the yield of dry matter, but the production of protein was smaller than without it. The increase in dry matter was insufficient to pay for its use. Phosphoric acid and potash favored the growth of clovers and proved most profitable, although the potash added comparatively little to the increase in yield.

**Some suggestions relative to alfalfa growing in Ohio**, C. G. WILLIAMS (*Ohio Sta. Circ.* 49, pp. 3).—Brief general directions for alfalfa culture are given.

The station found that on soil derived from sandstone the use of a ton of lime per acre was much more effective than other kinds of treatment, while on a limestone soil the application of lime gave no beneficial results. In some plot experiments on a limestone soil the use of 200 lbs. of steamed bone per acre seemed to have increased the yield over 148 per cent, while an application of 8 tons of stable manure per acre apparently gave an increase of 210 per cent.

**Alfalfa seed: Its adulterants, substitutes, and impurities and their detection**, H. F. ROBERTS and G. F. FREEMAN (*Kansas Sta. Bul.* 133, pp. 51-111, figs. 44).—The impurities commonly occurring in alfalfa seed are enumerated and described, and the results of purity and germination tests made by the station are recorded.

Seed of yellow trefoil (*Medicago lupulina*) was found to be the chief adulterant, but in a number of samples bur clover (*M. dentriculata*) and sweet clover (*Melilotus alba*) also occurred. It is pointed out that the seeds of these 3 species, unless present in large quantities, can not be readily distinguished from the seeds of alfalfa. Yellow trefoil and bur clover injure the quality of the forage produced, and on account of their being annuals die out after the first year and thus reduce the stand. Sweet clover is a biennial, and is generally distasteful to stock.

The chief impurity in western alfalfa seed is the dead seed of the alfalfa itself, and the obnoxious weed seeds most commonly present were chiefly those of species of docks and English plantain (*Plantago lanceolata*).

The range of germination in the samples ran from 60 to 96 per cent, with an average of about 83 per cent. The separation of dead alfalfa seed was not found practically possible, and it is recommended that the grading of alfalfa seed be based upon actual germination tests.

**Correction of a very unfavorable ratio of lime to magnesia in a soil for the culture of barley**, G. DAIKUHARA (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1 (1905), No. 1, pp. 13-16, pl. 1).—The soil originally contained 0.64 per cent. of calcium oxid and 1.91 per cent of magnesium oxid, representing a ratio of 0.34:1. By adding sufficient lime to make the ratio of these two substances 1:1 the yield of barley was doubled on well-manured soil, and even more than doubled when the manuring was one-sided or when no application at all was made. This result is attributed not only to the regulation of the ratio of lime to magnesia, but also to the improvement of the physical and chemical condition of the soil resulting from raising the lime content.

**Buckwheat**, J. L. STONE (*New York Cornell Sta. Bul.* 238, pp. 179-193, figs. 5).—This bulletin gives a general account of the buckwheat plant, with directions for its culture and uses.

An experiment was made by the station in 1901 to determine whether better results could be secured by turning rye under early in the season or by allowing it to grow until shortly before drilling in buckwheat. The results indicated that early plowing and subsequent harrowing to produce a thorough settling of the soil gives the better results. It is recommended that if early plowing is impracticable greater attention should be given to a thorough fitting of the seed bed.

The average yields in a variety test were as follows: Japanese 27.5 bu., Common Gray 26.8 bu., and Silver Hull 19.5 bu. per acre. In cooperative tests by 14 farmers in various parts of the State the average yield of Japanese was 21.29 bu. per acre and that of Silver Hull 20.05 bu.

**Buckwheat**, E. HACHELHOFF (*Landw. Vers. Stat.*, 63 (1906), No. 5-6, pp. 375-406, figs. 11).—A general description of the buckwheat plant, directions for its culture, a review of experiments conducted with the crop, and a discussion of the chemical composition of the grain, straw, and mill products, together with their feeding value, are given. A bibliography of 17 references is listed.

**The cassava industry**, L. COLSON and L. CHATEL (*Culture et industrie du manioc*. Paris: A. Challamel, 1906, pp. 95, figs. 7, map 1, dgm. 1).—This book treats of the culture of cassava on the Island of Réunion, and gives a résumé of the different operations necessary in the manufacture of starch and tapioca. Estimates are given on the cost of production of the crop and the manufactured food materials.

**Adulteration of red clover seed**, J. WILSON (*U. S. Dept. Agr., Office Sec. Circ.* 18, p. 1).—Of 521 samples of seed of red clover obtained in the open market 116 contained dodder and 5 were found to be adulterated with seed of yellow trefoil. These samples contained from 18.29 to 52.64 per cent of yellow trefoil.

**Corn**, W. H. SCHERFFIUS (*Kentucky Sta. Bul.* 122, pp. 155-189, pls. 3).—A method of selecting seed corn is outlined and a chemical study of the composition of a number of varieties of Kentucky corn is reported. Each variety is described and the results of analyses are given in tables.

These results show that the percentage of nitrogen does not differ materially in the individual whorls of grain on the ear, beginning at the butt, until after the middle is passed, when there is a gradual falling off in the nitrogen content toward the tip. In some instances, however, the grains at the tip contained a higher percentage of nitrogen than the grains in any part of the ear, while in other cases they contained the lowest.

In 3 samples of yellow corn with white-tipped grains scattered about over the ears, possibly due to cross fertilization, there was no material difference in the percentage of nitrogen of the white tipped and the yellow grains. The author concludes that this indicates that there is no change in the nitrogen content from the first year's cross fertilization. Longitudinal rows of grains on opposite sides of the ears gave approximately the same percentage of nitrogen.

**Experiments with corn,** C. G. WILLIAMS (*Ohio Sta. Circ 53, pp. 11, dgms. 2*).—The tabulated results of varieties of corn tested for 3 years show that many of them are not adapted to Ohio conditions. Experiments in thick and thin seeding pointed out that the increase in yield was very pronounced up to an average stand of 3.62 plants per hill, the rows being 42 in. apart each way, but that it was accompanied by a decline in average weight per ear, which was especially marked when more than 3 plants were grown per hill.

From field counts made in 63 counties by 328 correspondents it was estimated that the stand of corn in the State for 1905 was 83.6 per cent. The method of conducting an ear-row test plot is described in detail and the total yields of each row of a duplicate test of this kind is shown in a diagram. The yields from the different ears varied from 50 to 115 bu per acre. Notes are given on a score card for dent corn and on the selection of seed ears.

**Cooperative fertilizer experiments with cotton in 1901, 1902, 1903, and 1904,** J. F. DUGGAR (*Alabama College Sta. Bul. 131, pp. 17-74*).—In these cooperative experiments the station furnished material and instruction to farmers upon the agreement that the tests be made. The first year 10 reports were received, the second 13, the third 10, and the fourth 21. The conclusions and suggestions are based on these experiments and on earlier work.

The use of acid phosphate was found almost universally beneficial. Kainit, which was less frequently of benefit than acid phosphate, gave its best results where the crop was attacked by black rust. One hundred pounds of this substance per acre was usually found sufficient. The results indicated that on soils containing much clay kainit was unprofitable.

Cotton-seed meal proved to be very effective on all soils except on new land, or on soil rich in vegetable matter. For old lands a mixture of acid phosphate and cotton-seed meal, or of these two substances and kainit, is recommended. A small growth of stalks under favorable conditions of climate and culture is regarded as showing a deficiency of nitrogen in the soil, and a rank growth as indicating that only a small quantity or no nitrogen at all need be applied. The use of phosphates hastened maturity and the freshness of the land reduced the need for nitrogen. After a luxuriant growth of cowpeas or a recent heavy dressing with stable manure or cotton seed, applications of cotton-seed meal were superfluous. Fertilizer formulas for the cotton crop on various kinds of soils in different parts of Alabama are suggested.

**The great millet or sorghum in Madras,** C. BENSON and C. K. SUBBA RAO (*Dept. Agr. Madras Bul. 55, pp. 122*).—This bulletin gives a popular description of the crop and of the methods of its culture in Madras.

**Four-year culture tests with oats, 1901-1904,** W. EDLER (*Arb. Deut. Landw. Gesell., 1906, No. 114, pp. 370*).—The individual tests of cooperative experiments for the different years are described and notes are given on the 13 varieties compared. Strube oats gave in general the highest yields of grain, and especially good returns were secured under favorable moisture conditions.

In dry seasons Leutewitz Yellow ranked first in yield of grain, but in seasons with a greater moisture supply several varieties gave better yields. Beseler II succeeded only with a good supply of soil moisture, while Beseler III gave average results for the different years as compared with all the varieties tested. Duppau, Heine Prolific, Heine Trauben, and Anderbeck gave medium yields and were apparently not very readily influenced by weather conditions. Probstei and Fichtelgebirg produced medium yields under unfavorable conditions, but otherwise they were out-

ranked in productiveness by a number of sorts. Beseler I gave the lowest yield of grain, but with Strube ranked first in all years in straw production. Anderbeck and Selchow side oats were also heavy yielders of straw, while Selchow Panicle, Fichtelgebirg, Probstei, and Beseler III stood last in this regard.

A high percentage of grain was produced by Selchow Panicle, Beseler III, Duppa, Leutewitz Yellow, Probstei, and Beseler II, and a low percentage by Selchow side oats and Beseler I. Beseler II, Strube, Anderbeck, Probstei, and Duppa produced the heaviest grain, and Heine Trauben, Fichtelgebirg, Selchow side oats, and especially Leutewitz Yellow, the lightest. The liter weight of the grain varied considerably in different years and was quite irregular. Leutewitz Yellow and Beseler III were lowest in percentage of hull and Beseler II, Strube, and Fichtelgebirg highest.

The grain of Beseler I, Selchow side oats, Anderbeck, and Beseler II was richest in protein, while that of Fichtelgebirg and Leutewitz Yellow was poorest. Selchow side oats and Leutewitz Yellow outranked all other varieties in the fat content of the grain, and Leutewitz Yellow also ranked first in ash content. On the average, Fichtelgebirg ripened earliest, but showed the greatest tendency to lodge. Duppa, Strube, and Heine Prolific stood up well, and Selchow Panicle apparently produced the strongest straw. The Beseler varieties, together with Leutewitz Yellow, Heine Trauben, and Strube, proved quite smut-resistant.

The strong stooling varieties were Fichtelgebirg and Leutewitz Yellow, and the weak stooling sorts Strube, the Beseler varieties, Heine Prolific, and Selchow Panicle. The Beseler varieties produced the longest straw, and Fichtelgebirg, Strube, and Leutewitz Yellow the shortest. Anderbeck, the Beseler oats, and Strube were characterized in comparison with the other varieties by thick stems.

**A preliminary report on growing Irish potatoes, C. M. CONNER** (*Florida Sta. Bul.* 82, pp. 387-406, pls. 4).—A brief discussion of potato culture in Florida is given and the results of experiments in 1905 are tabulated but no conclusions are drawn from the data. The work consisted mainly of fertilizer tests to determine the best sources and the best quantities of the essential plant food elements.

Of different varieties tested Rose No. 4, grown from blossom ends, yielded 215 bu. and grown from stem ends, 225 bu. of marketable potatoes per acre. These were the heaviest yields secured. This same variety grown from Massachusetts seed yielded 160 bu., from Virginia second-crop seed 179 bu., and from seed grown at the station during the previous fall from small potatoes left from the spring crop, 89 bu. per acre.

**Some results of potato investigations in 1905, T. C. JOHNSON** ([*Quart.*] *Rpt. W. Va. Bd. Agr.*, 1 (1906), pp. 41-50).—Potato culture as carried on in West Virginia in the counties bordering on the Ohio River is described with reference to its extent on the bottom lands along the river, the fertilizer applications and crop rotation, the soil and its preparation, planting and cultivating the crop, harvesting and marketing, and the attacks of fungus diseases.

The principal varieties grown are Early Ohio, Carmen No. 1, Carmen No. 2, Green Mountain, and Sir Walter Raleigh. Experiments in spraying with Bordeaux mixture indicated that this was a profitable operation, a marked gain being shown in the production of the highest grade of tubers. With reference to that part of the crop consisting of small tubers spraying was unprofitable.

**A rough skin in its relation to the starch content of potatoes, R. KRZYMOWSKI** (*Jour. Landw.*, 54 (1906), No. 1, pp. 57-64).—Work on this subject by different investigators is reviewed and the author's own results are presented. The rough and smooth skinned tubers of 15 different varieties were analyzed and in 14 cases the rough-skinned tubers were richer in starch. The starch content of the smooth-skinned potatoes ranged from 16 to 19.2 per cent and that of the rough from 17.1 to 21.6 per cent.

**On the application of magnesia in the form of magnesium sulphate for the needs of the rice plant, G. DAIKUHARA** (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1

(1905), No. 1, pp. 23-29, pl. 1).—The results of pot experiments are reported which "show that in the presence of lime as carbonate the necessary amount of magnesia, when applied as crystallized sulphate for paddy rice in sand culture, is so small that the best ratio  $\text{CaO} : \text{MgO}$  becomes 30:1, while in the form of natural carbonates the best ratio would be 1:1 as Aso [E. S. R., 15, p. 1062] had ascertained. This conclusion will hold good also for various sandy soils, while for clayey soils the best ratio  $\text{CaO}$  as carbonate will differ."  
 $\text{MgO}$  as sulphate

Additional experiments, making comparative tests of sodium nitrate and ammonium sulphate, showed that the application of nitrogen as sodium nitrate was not favorable to rice plants, its relative value as compared with ammoniacal nitrogen being as 40 to 100.

**The anatomical structure of the stems of spring rye grown on moor soils and its change under the influence of manurial treatment**, P. VAGELER (*Jour. Landw.*, 54 (1906), No. 1, pp. 1-30).—The thickness of the stem wall was found to decrease from the base toward the top of the stem. All parts of the stem not protected by the leaf sheaths showed an evenly developed cuticle, but the epithelium was much strengthened in the upper parts of the stem and in the internodes.

At the lower joints of the internodes the stomata under the leaf sheaths remained inactive and there was practically no development of chlorophyll. The hypodermis was found strongest in the lower parts of the stems and in the internodes. The development of the parenchyma was greatest in the lower portions of the stem and in the upper parts of the internodes. The tissue through which protein is translocated prevailed near the head. The proportion of lumina to cell walls in the stem increased from below toward the spike, corresponding to the lesser strength requirements in the upper portions near the head.

The results of experiments to determine the influence of the fertilizer applications used showed that all manurial treatment, excepting the use of phosphoric acid by itself, tended to increase the size of the stem by enlarging the cell lumina at the expense of the cell walls. The parenchymatic tissue also increased with the quantity of fertilizer applied. Potash, without weakening the stem, favored the production of parenchyma and assimilative tissue and a reduction of unproductive tissue. Its use also resulted in a marked strengthening of the cuticle.

Nitrogen remained indifferent toward the length of the stem and the development of the fibro-vascular bundles, but it reduced the quantity of hypodermis, especially in the lower internodes. This result, coupled with a greater production of chlorophyll in the lower parts of the plant and a reduction in percentage of cell wall, weakens the stem. When nitrogen and potash were applied together the effect of weakening the cell wall was quite marked. Phosphoric acid given in excess produced exceptionally low yields. While acting favorably on the development of the framework of the plant, phosphoric acid reduced the total quantity of cell wall, but when applied with potash and nitrogen it had a strengthening effect on the plant.

**Experiments with sugar beet**, G. CLARKE (*Essex Ed. Com., County Tech. Labs., Chelmsford, 1906, Jan., pp. 22, pl. 1, figs. 3*).—Experiments were conducted at 5 different points. The average yield of sugar beets per acre was 18.3 tons, the percentage of sugar in the beet 16.7, and the purity 84.7. The results with Redtop sugar beet were not included in the average figures just given. This variety gave an average yield of 24.5 tons per acre, with 11.8 per cent of sugar and 79.2 purity.

**Seedling canes and manurial experiments at Barbados, 1903-1905**, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Imp. Dept. Agr. West Indies, Pamphlet 40, 1906, pp. 119*).—A summary of part of the work with sugar cane carried on under the direction of the Imperial Department of Agriculture is given.

The varieties of canes were grown on black soils in 12 cases and on red soils in 3. Cane B. 208 again gave good results as plant canes, especially on red soils. B. 147

outranked all the other varieties tested on the black soils. Of the newer varieties B. 1,529 stood second on both black and red soils. The results indicated that the application of nitrogen both to plants and ratoons is profitable. Sulphate of potash was also profitable, but phosphatic fertilizers either had no effect or decreased the yield.

**Report on experiments with varieties of swedes, 1902-1905, W. ALLAN** (*Edinb. and East of Scot. Col. Agr. Bul.* 7, pp. 15).—Twenty-four varieties of swedes were tested for 4 years. The varieties varied in productiveness and quality, productiveness being more inherent in the variety than quality.

The quality of the crop was influenced by the kind of soil, the size of the roots produced, and the variety grown. Wet and cloudy seasons reduced quality more than quantity. The best producing variety was Premier, which gave on an average fully 1½ tons per acre more than Conqueror, which stood next in the tests. In quality Kinaldie stood first, Stirling Castle second, and New Arctic third.

In the production of dry matter per acre Magnum Bonum and Queen ranked first and second, respectively, with an average difference of ½ cwt. per acre in favor of Magnum Bonum. Next to these varieties in the production of feeding material stood Premier, Paragon, and Stirling Castle.

**On the lime factor for the tobacco plant, G. DAIKUHARA** (*Bul. Imp. Cent. Agr. Expt. Sta. Japan*, 1 (1905), No. 1, pp. 17-22, pls. 3).—In order to determine the best ratio of lime to magnesia in a soil used for the growth of tobacco a series of pot experiments was made in which ratios of 1, 2, and 4 parts of lime to 1 of magnesia were used. The best results were obtained with a ratio of 4 parts of lime to 1 of magnesia. In all cases the tobacco plants were benefited by the application of lime.

**The results of seed tests at the German seed control stations** (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 11, pp. 121-123).—The number of samples tested and the average germination and purity at different seed control stations where this kind of work has been in progress for from 10 to 28 years are given in a table and briefly discussed.

Attention is called to the fact that salable beet seed must come up to the following requirements. A kilogram of beet seed must produce at least 70,000 sprouts in 14 days after planting, and of this number at least 46,000 must be produced in the first 6 days. Of 100 seed bolls not less than 75 must have sprouted in this time. The water content of the seed is considered normal up to 15 per cent, inclusive, and up to 17 per cent, inclusive, the seed may still be sold but a deduction in weight for the extra moisture content must be allowed.

Standard seed may contain 3 per cent of foreign matter, but when the content reaches 5 per cent a deduction in weight must be allowed. Over 17 per cent of moisture or more than 5 per cent of foreign matter in a beet sample makes it unmarketable according to the law.

**Report of the seed control station at Vienna for 1905, T. VON WEINZIERL** (*Ztschr. Landw. Versuchsw. Oesterr.*, 9 (1906), No. 3, pp. 279-382, pl. 1).—A review of the work of the station during the 25 years of its existence is given. During this period 200,867 determinations were made.

A list of 83 seed firms cooperating with the station is given, together with a register of the demonstration fields and forage plant and grass seed culture investigations established and in progress since 1898. The work conducted in the Alpine regions from 1890 to 1905 is described and the different investigations carried on in 1905 are noted.

**Studies of weeds. I, Some common thistles, J. PERCIVAL** (*Jour. Bd. Agr. [London]*, 12 (1906), No. 12, pp. 705-715, figs. 10).—The 4 common thistles *Carduus crispus*, *Chiclus lanceolatus*, *C. palustris*, and *C. arvensis* are described and figured and directions for the extermination of each species are given.

## HORTICULTURE.

**Pineapple culture. III, Fertilizer experiments, H. K. MILLER and A. W. BLAIR** (*Florida Sta. Bul 83, pp. 405-437, pls. 8, dgm 8*).—This bulletin contains the detailed plan and results of fertilizer experiments with pineapples, extending over a period of 5 years.

The purpose of the experiment was "to find out from what source or sources it is best to obtain fertilizing materials for pineapples; the proper quantity to use for the best results as regards quantity, quality, and shipping properties; best method of applying; ratio of phosphoric acid, nitrogen, and potash; the effect of shading, and to determine any other conditions which will prove of advantage to the industry."

The experiment contained 96 separate plats, with as many variations and combinations of the fertilizers commonly used for this crop. Each plat contained 100 plants and occupied  $1\frac{1}{10}$  of an acre. All the plats were covered with a lath shed, furnishing  $\frac{1}{3}$  shade. Preliminary to the work pineapples were analyzed with reference to the fertilizer constituents contained to determine the proportion in which they exist normally in the plant and fruit. The ratio of the constituents was found to be practically as follows: Phosphoric acid 0.8, nitrogen 1, and potash 2. The results secured on the different sections of the plats are discussed in considerable detail and illustrations given of the plants on many of the different plats.

Acid phosphate was found to have an injurious effect upon pineapples which could be corrected by the use of lime. It is thought that the acid phosphate itself was not the cause of the injury, but rather the sulphate of iron and aluminum which it contained, since acid phosphate derived from bone black did not have any injurious effect on the plants. Since, however, acid phosphate is occasionally colored to represent dissolved bone black, it is recommended that one not experienced in the use of fertilizers should not use any form of acid phosphate whatever for pineapples, but rely upon bone meal or slag.

On the whole the best results have been obtained by the use of about 3,750 lbs. per acre of fertilizer, analyzing 4 per cent available phosphoric acid, 5 per cent nitrogen, and 10 per cent potash, and this formula was perhaps best compounded by the use of bone, blood, and high-grade sulphate.

A number of fruits were analyzed to see if increasing amounts of fertilizer would affect their composition. The results obtained are tabulated, but the data are not considered sufficiently satisfactory to warrant conclusions.

Among the recommendations and conclusions drawn from the whole work, it is shown that as a source of phosphoric acid fine ground steamed bone, bone meal, and slag have given the best results. If acid phosphate is used lime should be added every year or two at the rate of 750 lbs. to the acre. "As sources of nitrogen, dried blood, cotton-seed meal, and castor pomace may be used. Nitrate of soda may be used for the first 6 months and possibly, to a limited extent, for the first year, but after the first year it will probably be safer to eliminate it entirely. Considerable caution is required in its use.

"Of the potash salts used, high and low grade sulphate have given the best results, the latter seeming slightly the better. Muriate has given fair results, though the sulphate undoubtedly gives better results. Kainit should not be used. High-grade tobacco stems, though not used in this experiment, have been used by a number of growers with good results.

"For most of the east coast soils we would recommend 3,500 to 4,000 lbs. to the acre annually of a fertilizer analyzing 4 per cent available phosphoric acid, 5 per cent nitrogen, and 10 per cent potash, to be applied at the rate of four applications a year for the first 18 months, and after this two applications a year; one in February or March, as the conditions may require, and one soon after the removal of the summer crop."

The use of a growing fertilizer on pineapples at the beginning of winter has been found objectionable, since when the plants are started into growth at this time, they are more easily injured by cold weather which may follow in January or February. Ground tobacco stems may be used in the fall, since this material does not cause much growth, but tends to the production, rather, of hardy plants, better able to withstand the cold.

"Within 3 weeks, or as soon as possible after setting out, the plants should have a light application of cotton-seed meal in the bud, about a tablespoonful to the plant. The first regular application should be put on broadcast about 6 weeks later, and be thoroughly worked in with the scuffle hoe." The experiment brought out clearly that when the quantity of fertilizer was increased from a little more than a ton to nearly 2 tons per acre, the number of larger sizes of pineapples was increased to a very profitable extent.

The pineapple crop was injured in 1905 by a frost in February, and some observations were made to determine the relation between the different fertilizers and the frost-resistance of the crop, but no satisfactory conclusions could be drawn.

**Pineapple culture. IV, Handling the crop,** H. H. HUME (*Florida Sta. Bul.* 84, pp. 441-457, pls. 5, fig. 1).—In the 3 preceding bulletins on this subject, soils, varieties, and results of fertilizer experiments have been considered (E. S. R., 14, p. 459; 15, p. 468; 17, p. 1154). In the present bulletin the author considers the subject of packinghouses and their equipment, field equipment for the harvesting of pineapples, pineapple packages, harvesting, grading, shipping, and marketing fruit with special reference to Florida conditions.

Relative to the picking of pineapples the author states that before reaching full maturity the pineapple is dark, black-green in color and the eyes somewhat pointed and angular. As maturity advances the eyes flatten down somewhat in the center and become slightly elevated around the margins, and the color changes to a very pale green. "The opening and spreading of the crown may be taken as one of the best indications of maturity. . . . As the fruit ripens the stem elongates, the slips grow rapidly and their leaves spread out." In summer fruit intended for short-distance shipments and immediate consumption the basal eyes may be allowed to retain some color. "If considerable time is to elapse between picking and consumption, the fruit should not be quite so mature."

**The mango in Hawaii,** J. E. HIGGINS (*Hawaii Sta. Bul.* 12, pp. 32, pls. 10).—A popular treatise on the culture of mangoes in Hawaii. In some experiments made to determine the longevity of mango seeds it was found that of seed 31 to 41 days old, 43.5 per cent germinated and produced good plants. These figures indicate that the seed can be preserved much longer than is generally supposed. An analysis is given of the mango, which shows it to contain 82.51 per cent water, 0.39 per cent ash, 0.01 per cent fat, 1.45 per cent fiber, 0.84 per cent protein, and 14.80 per cent carbohydrates.

Directions are given for the manufacture of chutney, marmalade, and jelly from mangoes, and notes are given on mango breeding, diseases and insects affecting mangoes, varieties of mangoes, and mango seedlings in Hawaii.

**Vegetable novelties,** F. W. RANE and H. F. HALL (*New Hampshire Sta. Bul.* 125, pp. 155-180, figs. 27).—The results are given of tests of some of the more recent varieties of beans, beets, cabbage, carrots, sweet corn, cucumbers, lettuce, watermelons, pumpkins, squash, potatoes, and tomatoes, with brief descriptive notes. Nitro-culture was used without success in the growing of beans and peas.

**Horticultural division,** G. S. SCOTT (*Orange River Colony Dept. Agr., Ann. Rpt.*, 1 (1904-5), pp. 169-181).—Notes on a large number of fruits planted at various government forestry stations, and of the growing of certain vegetables, particularly potatoes, on the same area.

**Flower biology and productiveness of fruit trees**, EWERT (*Landw. Jahrb.*, 35 (1906), No. 1-2, pp. 259-287, pls. 2).—Results of extensive experiments are given in which the productiveness of apples and pears, as related to the biology of flowers, was investigated. The special point studied was whether there is anything to fear from the standpoint of self-sterility in making large plantings of a single variety. The following conclusions from the author's work, which extended over a period of 3 years, will show the problems on which data were secured:

Numerous seeds and increased size of fruit accompany each other. Seedless fruits occur not only on such seedless varieties as Vaterapfel and Rihas Seedless, but frequently on trees that usually produce fruit with seeds. Seedless fruits grown on the same tree in competition with seeded fruits are smaller than the latter and frequently misshapen. If foreign pollen is withheld from a tree and only seedless fruits produced, these fruits reach the same size as fruits with seeds. In plantings of a single variety the number of seedless fruits and fruits with but few seeds is relatively high. More fruits with than without seeds are found, however, which indicates that even under such difficult conditions, foreign pollen is carried to the blooms in considerable quantities. Waite's division of fruits into self-fertile and self-sterile sorts requires revision, since fruits may be formed in the absence of pollen.

The experiments which have been made to determine the effect of self-pollination on individual branches of a tree are often of negative value because the enclosing of the blooms results in an unfavorable physiological condition and seedless fruits formed on such branches must compete for nourishment with the seeded fruits on other branches.

There is no basis for the fear that large plantings of a single variety in Germany will result in a decreased yield. The ability of pollen to germinate is variable, but may endure for more than 3 weeks.

**Fruits and other food products of Jamaica**, E. J. WORTLEY (*Jamaica: Gleaner Co., Ltd.*, 1906, pp. 73, pls. 2).—Brief descriptions and notes are given on the more usual fruits and vegetables grown in Jamaica, as well as such subjects as cloves, coffee, kola, vanilla, sugar cane, etc. The plates show the fruits of all the different plants described.

**Influence of colored light on the preservation of ripe fruit** (*Mark Lane Express*, 94 (1906), No. 3889, p. 399).—In an article abstracted from the *Bulletin of Agricultural Information*, the results of some experiments are given in which it is shown that ripe fruit can be kept for a longer time under blue glass than under ordinary circumstances. In the experiments cited strawberry plants were grown in pots, and when ripe, part of the pots were placed under red glass and part under blue glass. After a couple of days the fruit under the influence of red light was completely spoiled, while those under blue light kept in good condition for 7 days.

**Orchard notes**, W. M. MUNSON (*Maine Sta. Bul.* 128, pp. 65-80, pls. 4).—Under the above heading notes are given on spraying, insects and diseases affecting apples, winter injuries to apple trees, nice injuries, and suggestions given as to pruning trees and handling fruit.

The injuries to apples following the severe winters of 1903-4 and 1904-5 were thought to be due to the overbearing of the trees following a dry season and the very cold winter. Trees which were well-cultivated and fertilized started a vigorous growth near the base of the main limbs from which it will be possible to build a new top. In neglected orchards or where the thrifty trees were left in sod, the injured trees continued to deteriorate and many have died. In order to prevent future winter injury it is suggested that the trees be not allowed to overbear.

If tar paper is used to protect trees from mice injuries, it is considered important that the paper be removed in the spring; otherwise there is danger of the tree scalding. The cost of sufficient wire screen to protect 400 young trees was \$7.60. The tar paper for an equal number cost 84 cts. Strips of wood veneer, which cost

\$5 per thousand, were also used successfully, but in applying them the work must be done before freezing weather comes or many of them will crack and be useless. A still cheaper form of protection is a coat of paint, providing pure materials are used.

An obscure physiological disease of apple trees, apparently due to the excessive use of nitrogenous fertilizers and the lack of available potash, is briefly described.

**The apples of New York, II**, S. A. BEACH, N. O. BOOTH, and O. M. TAYLOR (*New York State Sta. Rpt. 1903, pt. 2, pp. IV + 360, pls. 84*).—This volume is similar in make-up to the preceding (*E. S. R.*, 17, p. 559), and is devoted to summer and fall apples which have originated or are grown in New York. It contains an index of the varieties mentioned in the volume, and also a combined index to volumes 1 and 2.

**Apple districts of New York with varieties for each**, U. P. HEDRICK, N. O. BOOTH, and O. M. TAYLOR (*New York State Sta. Bul. 275, pp. 61, map 1*).—An alphabetical catalogue is given of the apples that have grown or have originated in New York, in which the characteristics and season of each variety are noted, its suitability for different sections of the State pointed out, and general remarks given on its usefulness.

In addition a discussion is given of the distribution of varieties of apples and the adaptation of groups of apples. Under the latter heading a large number of varieties of apples have been classified into groups, such as Aport Group, Baldwin Group, Early Harvest Group, Fameuse Group, etc. New York State is divided into 9 pomological districts, and lists of varieties which may be successfully cultivated for different purposes given for each. A list of varieties of apples which are unworthy a place among the apples of New York is included in the bulletin, as well as a list of those which have not been sufficiently tested to justify comment on them.

**Peach and plum culture**, A. B. MCKAY (*Mississippi Sta. Bul. 93, pp. 16, figs. 3*).—An account of the laying out, planting, and yields of a 9-acre peach orchard, 6 acres of which was planted for commercial purposes with 900 Elberta and 50 Triumph peach trees, and the remaining 3 to numerous varieties of peaches and plums.

The orchard was planted during the first days of January, 1898. In 1899 the trees were severely frozen, so that the bark from the ground to the crotches of the lower branches could be easily pulled away from the tree. They were severely headed back and entirely recovered.

Three crops of peaches have been secured from the commercial orchard. The yield in 1901 was 550 bu.; 1902, 520 bu.; and in 1904, 1,575 bu. The total net returns from the shipment of these fruits to St. Louis, Chicago, and St. Paul were \$2,500. The first year the orchard was set out sweet potatoes were grown between the rows, and yielded at the rate of 100 bu. to the acre. The next season peas were planted between the rows, and yielded at the rate of 20 bu. per acre. The total receipts from these crops amounted to \$390. The cost of the trees and the expense of preparing the land and planting was \$66.75. The care of the orchard is placed at \$270, making a total expense of \$336.75.

There was, therefore, a profit on the crops grown in the orchard of \$53.25, which may be regarded as a good rental value on the land for 3 years, at the end of which time the orchard was ready for fruit-bearing, free from encumbrances. For the next 4 years the average returns from the orchard and fruit were \$625, or \$104.16 per acre. The annual expense of caring for the orchard during this period is placed at \$30, leaving a clear gain of \$74.16 for each acre during the 4 years.

Brief descriptions are given of 20 varieties of peaches, and of 7 varieties of plums grown in the experimental orchard. Relative to the fruit produced on different kinds of soil, the author states that trees on the stiff, heavy clay over a light-colored, sticky and poorly drained subsoil made a rather unhealthy growth, a large percentage of the trees died, and the fruit lacked color and flavor. "On the deep, strong clay loam

over an orange-colored clay subsoil the trees have grown rather too vigorously." It has been difficult to keep wood growth within proper limits, but "rather more fruit has set on these trees than in other parts of the orchard."

On light, grayish-colored soil the trees are medium sized, require but little pruning, and produce a fair amount of fruit of good quality, but show signs of nearing the end of their period of usefulness. On red clay over deeper red subsoil "the trees are of medium size, but healthy, well shaped, and require but little pruning. The fruit on this section is invariably more highly colored, freer from defects, more uniform in size and shape, and more highly flavored than that from other parts of the orchard."

**Peaches for home and market**, W. J. GREEN and F. H. BALLOU (*Ohio Sta. Bul.* 170, pp. 157-186, figs. 35).—Popular directions are given for the culture of peaches, including recommendations as to the soil and its preparation, location, trees, planting, cultivation, fruit thinning, etc., with brief descriptions of 30 of the better sorts.

**Varieties of strawberries and cultural directions**, O. M. TAYLOR (*New York State Sta. Bul.* 276, pp. 63-79).—The author describes 27 of the standard and newer varieties of strawberries which have been grown at the station, and gives brief cultural directions for strawberries.

In 1905 the season was specially favorable at the station for a good strawberry crop. Fairfield and Weston No. 1 were among the earliest of the desirable kinds. Weston No. 1 produced large fruit of desirable size to the close of the season, but Fairfield appeared to be valuable only on account of its earliness. Among the latest sorts were Cardinal, Mark Hanna, Mead, President, Ridgeway, and Rough Rider. All of these, except Cardinal, produced large fruit of desirable size to the close of the season. The author suggests that the varieties Joe and Mead should be planted closer than other varieties. Mark Hanna was the most productive, though low in quality. President was of largest size and an excellent show berry, but deficient in quality. Mark Hanna yielded at the rate of 12,400 qts. per acre, while Midnight, the least productive variety, produced but 1,114 qts. per acre.

**Strawberries**, O. M. TAYLOR (*New York State Sta. Bul.* 276, popular ed., pp. 8).—A popular summary of the bulletin noted above.

**Marketing strawberries** (*Country Gent.*; 71 (1906), No. 2780, pp. 450, 451).—An account of a successful cooperative society for marketing strawberries, located at Neosho, Mo., with some details as to methods of marketing and doing business.

**Longevity of grapes of various varieties and species in north Texas**, T. V. MUNSON (*Texas Farm and Ranch*, 25 (1906), No. 7, p. 5).—The author gives the results of growing 69 varieties and species of grapes for 19 years in Texas, on a light sandy soil from 6 in. to 3 ft. deep and resting on red and yellow clay subsoil. The data are largely given in tabular form. They show the names of each variety, its specific blood, the number of vines of each variety planted 19 years before, number and percentage of vines now alive, degree of profitableness, diseases affecting and present condition of each variety.

The author considers the native Post grape (*Vitis lincedum*) the most valuable of all American species in many respects. It therefore has been used extensively in hybridizing. The article refutes the statement of H. M. Stringfellow to the effect that the Aestivalis types of grapes are the most reliable in the interior of Texas. The tabular data given show a number of varieties superior to these.

**Varieties and species of cultivated cacao**, M. A. FAUCHÈRE (*Jour. Agr. Trop.*, 6 (1906), No. 57, pp. 76-79).—Brief descriptions of varieties and species of cacao, with an account of their respective uses.

**Second report on pecan culture**, H. H. HUME (*Florida Sta. Bul.* 85, pp. 463-501, pls. 8, figs. 14).—This is a popular bulletin on the pecan, dealing with its botany and culture in Florida. Such matters as propagation, grafting, nursery growing, top-working, preparation of soils, the planting of the orchard, cultivation, fertilizers to use, methods of pruning, harvesting, marketing, and varieties, are considered in

detail. It is similar in character to the two previous bulletins issued on this same subject (E. S. R., 11, p. 57; 12, p. 559).

Relative to budding the author states that the buds now commonly used are those which have been formed just previous to the time of budding. The recommendations of Oliver (E. S. R., 14, p. 968) that dormant buds of last season be used, has not met with favor in Florida because of the large amount of wood which must be sacrificed to secure a few buds. The best trees for planting in the pecan orchard are well grown 1-year-old trees, from 3 to 5 ft. high. The best time to plant is in the latter part of November to the first of February. The 10 varieties which the author believes worthy of cultivation in Florida are described and notes given on their origin.

**All the spireas worth growing**, J. DUNBAR (*Gard. Mag.* [N. Y.], 3 (1906), No. 4, pp. 206-210, figs. 8).—Of the 50 species of spireas in cultivation in the United States only 14, in the author's opinion, are worth cultivating, and these belong to two great natural groups, the early bloomers, which are white flowered, and the late bloomers, which are some shade of pink, with two exceptions.

The first group is pruned in June; the second in winter. These 14 species are divided into 5 flowering types, each of which is illustrated. The culture of spireas is given, with descriptions of each species of importance. A systematic key or guide is given to the horticultural value of these species.

**The American carnation**, A. HEMSLEY (*Gard. Chron.*, 3. ser., 39 (1906), No. 1002, pp. 145, 146).—The author states that the introduction of the variety Mrs. T. W. Lawson in England has led to the extensive cultivation of American carnations in England, and that the American varieties are far in advance of the English. A number of varieties are described and methods of cultivation discussed.

**Further experiments on inheritance in sweet peas and stocks**, W. BATESON, E. R. SAUNDERS, and P. C. PUNNETT (*Proc. Roy. Soc.* [London], Ser. B, 77 (1906), No. B 517, pp. 236-238).—Some of the peculiarities in color inheritance among sweet peas and stocks are pointed out as the result of experimental investigation.

## FORESTRY.

**The forestry work of the Ohio Experiment Station**, W. J. GREEN and C. W. WAID (*Ohio Sta. Circ.* 50, pp. 11, figs. 5).—A considerable amount of cooperative forestry work with farmers is being undertaken. In all 355 plats have been planted to forest trees in different parts of the State under the supervision of the station.

The plan is to give aid to those who wish to help themselves rather than to carry on large forestry operations independently. Some forestry work is being done at the station. In all about 9 acres have been planted to *Catalpa speciosa*, black or yellow locust, Osage orange, white ash, green ash, larch, black walnut, and mulberry. Seedling trees are furnished by the station to farmers without cost.

It is stated that in a catalpa grove 23 years old, the timber value was \$326, or \$14.17 per acre for each year since planting. In the case of the locust grove 19 years old, the value was \$341.76, or \$17.98 per acre for each year since planting.

**Forest planting in the sand-hill region of Nebraska**, G. PINCHOT (*U. S. Dept. Agr., Forest Serv. Circ.* 37, pp. 5).—The results of experiments in growing pine trees on the sand hills of Nebraska seem to indicate that western yellow and jack pine can be successfully used in this region.

The best of the jack pine trees set out on the Bruner plantation in 1890 are now 18 to 30 ft. high. The western yellow pine (bull pine) although not as fast growing as jack pine, is longer lived and is a more valuable tree when matured, and is equally well adapted to the region for planting. Suggestions are given on where to secure planting material and methods of planting. The cost of wild jack pine seedlings is placed at \$5 per thousand delivered, and of yellow pine \$6 to \$15 per thousand. The cost for material and labor is placed at \$2.30 per acre.

**Review of forest administration in British India,** S. EARDLEY-WILMOT (*Rev. Forest Admin. Brit. India, 1903-4, pp. 63, maps 2*).—In addition to the usual data regarding forestry affairs in 1903-4, a 5-year review is given of forestry conditions in India, in which it is shown that the forest area has increased from 81,869 square miles in 1899 to 96,466 square miles in 1904. The working plans at the end of 1904 covered 33,680 square miles. The total cubic feet of timber and fuel cut during this period was 236,016,000. At the same time 214,505,000 bamboos were cut, and the minor forest products amounted to 4,756,000 rupees. The total revenue for the 5-year period was 19,658,000 rupees; the total expenses, 11,269,000 rupees.

Relative to the Imperial Forest School, it is shown that, since its establishment in 1899, 673 students have gone out of the school, of whom 418 are now in government service, 135 in that of native states, etc. The average cost of education per head is 2,606 rupees, without taking into consideration the cost of the buildings.

The appendixes contain the usual data in regard to the forest survey operations, expenditures, receipts, etc. Two large maps of India are given, one showing the distribution of forest lands in India, and the other the forest survey working plans now in operation.

**How shall forests be taxed?** A. GASKILL (*Forestry and Irrig., 12 (1906), Nos. 3, pp. 119-122; 4, pp. 172-177*).—A paper read before the Society of American Foresters, in which inequitable taxation is held responsible for much of the present forest destruction. Suggestions are given as to the principles which should be applied in the taxation of forests. European systems of taxation are briefly noted.

The author holds that forests should be assessed apart from the land on which they stand, and since they are of public benefit the commonwealth should bear a part of the cost of maintaining them—that is, the State should be made to contribute its share of the cost, as well as the counties in which the forests are located. The greater part of the tax on the forest should fall due when the timber is sold, and the deferred tax should bear a fair relation to the net yield of the property. The owner is entitled to a fair annual return on his investment.

In the enactment of future tax laws relative to forest property, three considerations should enter. "(a) Necessity—the support of the local government; (b) equity—an assessment based upon the actual yield, collection of the tax (on the trees, not on the land) deferred until the crop is sold, and a recognition of the peculiar risks—fire, trespass, etc.—to which forests are subject; (c) encouragement—a special rating of the property to compensate the owner for whatever expense attaches to maintaining the forest in a condition that best serves the public interest."

**Kealia forest reserve** (*Hawaii. Forester and Agr., 3 (1906), No. 2, pp. 61-68*).—This proposed forest reserve contains 9,935 acres. Its purpose is to protect the natural forest covering the watershed of the northern end of the Puna District of Kauai. A description is given by the superintendent of forestry, R. S. Hosmer, of the lands and forests included.

**Ewa forest reserve** (*Hawaii. Forester and Agr., 3 (1906), No. 2, pp. 68-79*).—Recommendations, with resolutions relating to the establishment of Ewa forest reserve, are given, with a report by the superintendent of forestry on the area of land included, and an account of the forest. The purpose of the reserve is to insure the continuance of the forest on the Koolau Mountains, and to increase its efficiency as a protection forest by bringing the area under a system of forest administration. The total area of the whole reservation is approximately 28,550 acres.

**The black wattle in Hawaii,** J. G. SMITH (*Hawaii Sta. Bul. 11, pp. 16, pls. 3*).—The results are given of harvesting a 6-acre grove of Australasian black wattle (*Acacia decurrens*) about 13 years old, and directions given for the cultivation and harvesting of this tree in Hawaii. Some data are also given on the influence of climate on the tannin content of black wattle, the production of tan-bark extracts, details of

tanning processes, and suggestions on what to do with the wood. The insect enemies of black wattle in Hawaii are briefly enumerated by D. L. Van Dine.

The wattle appears to thrive best in Hawaii on rather heavy soils at an elevation of 800 to 3,000 ft., where the rainfall ranges from 80 to 150 in. per annum. The 6-acre tract harvested grew on a steep slope at an elevation of 600 to 800 ft. It yielded 38 tons of bark. The 36 tons which were sold brought \$839.44, and in addition 500 fence posts and 88 cords of firewood were secured. The firewood was sold for \$689.25, making the total value of the tract a little over \$1,600. The trees at this time had reached their full development and during the preceding 4 years about 20 per cent of them had died, some because they had reached their limit of growth, and others on account of injury from stock and insects.

Under methods of cultivation, it is stated that 1 lb. of seed will plant 10 acres. Before planting, the seed should be either covered with boiling water and allowed to stand 24 hours, or scorched in hot ashes to soften the hard outside skin to facilitate germination. It is considered more economical to plant the seed in place than to sow in nursery rows and transplant. The trees on good soil should be ready to cut in 10 years. In the station grove trees of the same age varied from 18 in. at the butt, when growing on rich soil with heavy rainfall, to only 6 in. in diameter on rocky thin soil at a lower and drier elevation. Ten-year-old trees should yield at least 100 lbs. of green bark, equal to 50 lbs. of dry bark. It is considered doubtful whether black wattle can be profitably cultivated except on land of fairly good character.

The best bark was obtained by drying under roofs. The main point seems to be to dry in such a manner that the bark will not mold. Where sufficiently large areas are to be harvested, the author believes it would pay to build a large drying house carrying temporary slatted floors 18 in. apart, on which the green bark, cut into lengths of 2 or 3 in., could be uniformly distributed for drying.

In investigating the influence of climate on the tannin content it was found that in the case of koa bark (*Acacia koa*), that taken from trees above Hilo showed 17 per cent tannin, while samples taken from a much drier district showed only 12 per cent. Samples of wattle bark taken from trees growing in a very wet district showed fully as high tannin content as trees growing in a very dry district. The range of tannin in this bark varied from 25 to 36 per cent. No apparent relation was found between the tannin content and the soil or season. The highest yield, therefore, of tannin per acre can be secured from lands on which the trees during the normal growth will produce the largest amount of bark, and this is likely to be obtained where the rainfall is sufficiently heavy to afford the trees uninterrupted growth.

The wood is stated to be hard and tough, and comparable with algeroba in fuel value, but somewhat more difficult to split. It checks in drying. Some suggestions are given on its use in making wood alcohol. It is estimated that 200 acres of ground planted to black wattle would yield 500,000 cu. ft. of wood in 10 years. By distillation this would give a minimum of 1,650 tons of charcoal, 15,000 gal. of wood spirits, 380 tons of acetate of lime, and a large amount of wood tar and creosote, having a total value of \$44,000, while the cost of production should not exceed \$20,000.

**How to prune young locust and catalpa trees,** W. J. GREEN and C. W. WAID (*Ohio Sta. Circ. 51, pp. 6, figs. 3*).—Locust trees are nearly self-pruning. They have a tendency to produce one fork and if this is removed, no attention need be paid to the smaller limbs. With the catalpa the authors recommend the cutting off of the tree to the level of the ground when 2 or 3 years old and allowing but one sprout to develop from the stump. If the trees have made a good root growth, they may be cut back the second year, but if not, pruning should be deferred until the third year. Late winter or early spring is considered the best time for cutting back.

**Northern limit of the papaw tree**, C. A. WHITE (*Science*, n. ser., 23 (1906), No. 593, pp. 749-751).—A discussion of the distribution in the United States of the papaw (*Asimina triloba*), persimmon, and pecan.

**Packing seeds for the Tropics**, J. H. HART (*Gard. Chron.*, 3. ser., 39 (1906), No. 1010, pp. 275, 276).—The author calls attention to the necessity of packing seeds intended for the Tropics in dry air and in tinfoil packets in order to preserve their ability to germinate. He cites an instance in which English peas imported into Trinidad in ordinary packets gave a 95 per cent germination when first sown. The sowing a month later gave 75 per cent. At the third sowing, 30 days later, the percentage of germination was 40, and at the fourth sowing the percentage of germination was but 20.

**Suitability of New South Wales timbers for railway construction** (*Indian Forester*, 32 (1906), No. 2, pp. 74-77).—This is a review of the report of the forestry branch of New South Wales for 1904-5.

It appears that the timber area of commercial value in New South Wales is about 20,000,000 acres, or 10 per cent of the area of the State. Up to 1904 about 7,503,200 acres of the forest area had been examined and reserved from sale. The value of the timber exported has risen from \$225,145 in 1895 to \$794,230 in 1904. Ironbark is used largely for piles, trams, girders, and transoms of bridges because of its strength and durability. Tallowwood, gray and red gum, blackbutt, and Sydney blue gum for decking and light scantling, and turpentine and ironbark for jetty and pier work.

Under favorable conditions ironbark has lasted 40 years as bridge timber, and turpentine piles have been found perfectly sound after standing 40 years in salt water. It is stated that Australian hardwoods last much longer in the track than the timbers commonly used in Europe and North America.

**Report on the turpentine industry in the United States**, BELL (*Diplo. and Cons. Rpts.* [London], Misc. Ser., No. 647, pp. 17).—A report on the turpentine industry in the United States by the British commercial agent, the data for which are largely based on the reports of the U. S. Department of Agriculture.

## DISEASES OF PLANTS.

**Notes on miscellaneous diseases**, K. MALKOFF (*Ghodiashen Otchet Drzhavnata Zeml. Opitna Stantziya Sadovo*, 2 (1904), pp. 156-233 [German Summary], pp. 19-22, pls. 3).—Notes are given on a number of diseases and insect injuries of economic plants.

Among the subjects treated are the spot disease of chick-peas due to *Ascochyta pisi*, which the author says may be controlled with Bordeaux mixture; the control of plum pockets with 3 per cent Bordeaux mixture; combating rose rust with Bordeaux mixture; the brown rot of plums (*Monilia fructigena*); a bacterial disease of mulberries; the use of Paris green, tobacco extracts, etc., against insects; and critical notes on plant diseases observed in Bulgaria in 1904.

**Laboratory notes**, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, 13 (1905), pp. 405-428, pls. 19, figs. 5).—Brief descriptive notes are given on a number of diseases of plants. Among them are a disease of Swedish turnips (*Phoma napo-brassicæ*), apple and pear canker (*Nectria ditissima*), apricot coral spot (*N. cinnabarinna*), onion mildew (*Peronospora schleideni*), bean anthracnose (*Colletotrichum lindemuthianum*), broad bean rust (*Uromyces fabæ*), hollyhock rust (*Puccinia malvacearum*), a number of diseases of roses, club root of cabbage (*Plasmidiophora brassicæ*), etc.

**Contribution to the life history of some Uredineæ**, E. FISCHER (*Centbl. Bakt.* [etc.], 2. Abt., 15 (1905), No. 7-8, pp. 227-232).—Notes are given on *Pucciniastrum padi* and *Puccinia liliacearum*.

**Investigations on the stinking smut of wheat and its control**, K. MALKOFF (*Ghodiashen Otchet Drzhavnata Zeml. Opitna Stantziya Sadovo*, 2 (1904), pp. 139-149,

[*German Summary*], pp. 12-14).—The author investigated the effect of time of seeding on smut production, seed treatment with fungicides, and varietal resistance. No striking differences could be noted in the amount of smut that could be attributed to the time of seeding.

In the experiments for seed treatment the effect of hot and cold ashes, dry air, cold water and milk of lime, Bordeaux mixture, hot water, copper sulphate solutions, formalin, and corrosive sublimate solutions were tested. All the treatments reported diminished the germinative ability of the wheat to some extent, the least injury reported being with the lots of seed treated with 0.1 per cent formalin, followed closely by the lot soaked for 5 minutes in Bordeaux mixture. The seed of the different lots was sown and counts made of all smutted stalks and heads.

Practically all smut was prevented by the treatments with Bordeaux mixture, formalin, and 0.5 per cent copper sulphate solution, each treatment being about the same in efficiency. Mixing the grain with dry ashes immediately after thrashing was next in efficiency, only 3.5 per cent of the plants and 2.5 per cent of the heads being smutted.

Marked differences in varietal susceptibility are noted.

**Investigations on the mosaic disease of tobacco**, F. W. T. HUNGER (*Ztschr. Pflanzenkrankh.*, 15 (1905), No. 5, pp. 257-311, fig. 1).—A review is given of the various theories regarding the cause of the mosaic disease, particular attention being given the bacterial theories of Mayer, Iwanowski (E. S. R., 13, p. 361), and Prullieux and Delacroix (E. S. R., 5, p. 1019), and the theories of Beijerinck (E. S. R., 10, p. 1058), and Woods (E. S. R., 13, p. 146; 14, p. 264), after which the author states and elaborates his theory regarding the causes of this disease.

According to the author's view any disturbances in the normal metabolism of the plant may result in the variegation characteristic of the mosaic disease. He holds that the immediate cause of the disease is an unorganized ferment of the toxophore group of Oppenheimer rather than oxidizing enzymes, as proposed by Woods and others. The mosaic disease must not be confused with variegation as it occurs in ornamental plants, which has been shown to be a not infrequent phenomenon in certain species of *Nicotiana*. It is also said to differ from the disease described by Sturgis under the name "calico" (E. S. R., 11, p. 755).

Some of the factors favoring the mosaic disease are described and the results of investigations on meteorological conditions and soils in Java are given. A bibliography of literature relating to this subject completes the article.

**Combating the mosaic disease of tobacco**, H. JENSEN (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 13-14, pp. 440-445).—In commenting upon the possibility of combating the mosaic disease through breeding experiments, the author briefly describes an experiment which he thinks shows the impossibility of producing resistant races within a single year, as has been claimed by others.

The author believes it will be possible to develop resistant varieties, but that it will be found best to work with resistant races within varieties of known quality, rather than attempt to develop new types whose chief recommendation is hardness or resistance.

**Potato diseases**, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, 13 (1905), pp. 346-363, pls. 6, figs. 2).—A brief account is given of spraying experiments which successfully reduced the percentage of loss due to various potato diseases, and descriptions are given of the following diseases of potatoes: Late blight (*Phytophthora infestans*), early blight or leaf curl (*Macrosporium solani*), bacteriosis (*Bacillus solanacearum*), scab (*Oospora scabies*), dry rot (*Fusarium oxysporum*), a wet rot which is believed to be of bacterial origin, and brown spot, which is of an uncertain cause. Where known, suggestions are offered of means for preventing these diseases.

**Note on the facultative saprophytism of *Alternaria solani***, A. H. COCKAYNE (*New Zeal. Dept. Agr. Ann. Rpt.*, 13 (1905), pp. 428-430).—A report is given of a

series of experiments with *Alternaria solani* to determine whether it has lost its power of developing saprophytically.

Healthy leaves and leaves infected with *Phytophthora infestans* were inoculated with conidia of *A. solani*, and after developing, the spores were gathered and sown on leaves attacked by the late blight. These infections were repeated for six generations, when the conidia were sown on healthy leaves and kept in a damp chamber. The conidia germinated freely, but the mycelium was poorly developed and no spotting of the leaves resulted, the mycelium appearing to live almost entirely on the surface of the leaves.

It appears that through a space of six generations this fungus, which has become parasitic, was so reduced through gradual adaptation as to be converted into an obligate saprophyte.

**Heart rot of beets, mangels, and Swedish turnips** (*Jour. Bd. Agr. [London]*, 12 (1906), No. 10, pp. 596-598, fig. 1).—A description is given of a disease, attributed to the fungus *Sphaerella tabifica*, which is said to be not uncommon in France, where it causes considerable damage to sugar beets. In England the fungus has recently made its appearance, being particularly destructive to mangels and Swedish turnips.

The disease rarely appears before the middle of August, and first attacks the stalks of the largest leaves. Its presence is indicated by the wilting of the leaves, such as follows a hot, dry day; during the night the diseased leaves do not recover, but remain lying on the ground, turn yellow, and decay. Later in the season, when the leaf stalks are dead and dry, a second form of fungus fruit appears on the bleached patches, and some time later the mycelium of the fungus passes into the crown of the root, gradually extending downward. Finally the entire root is reduced to a blackish decayed mass.

The fungus seems to be able to pass the winter in diseased roots left in the field, and where the disease appears, it is recommended that the crop should be harvested immediately and all diseased leaves and roots gathered and burned or deeply buried.

Yellow varieties of mangels appear to be more susceptible to disease than others, as shown by infection experiments.

**The drop disease of cabbage**, J. RITZEMA BOS (*Tijdschr. Plantenziekten*, 11 (1905), pp. 105-117, pls. 3).—A description is given of a disease of cabbage said to be due to *Phoma oleraceae*. It has appeared in some of the most important cabbage growing districts of Holland and is proving quite destructive.

**Three fungus diseases of the cultivated ginseng**, H. S. REED (*Missouri Sta. Bul.* 69, pp. 43-66, figs. 9).—According to the author, ginseng plantations have increased in number and extent so that ginseng now constitutes an important crop in the State.

The first occurrence of disease on ginseng plants was reported in 1904. At that time the disease seemed to be due to a leaf-spot fungus, and it was thought that spraying with Bordeaux mixture might keep it in check. Later investigations showed that a number of diseases were present and they were not similar to those described from New York (E. S. R., 16, p. 271). On this account the author made a detailed study of the diseases and the fungi causing them. The diseases described are stem anthracnose, leaf anthracnose, and wilt.

The stem anthracnose is due to the fungus *Vermicularia dematium*, and it makes its appearance about 30 days after the plants appear above the ground, producing numerous black scars on the stems of the plants. The stalks are frequently so badly attacked that they break off before the upper portions become wilted. The direct injury is due to the filaments penetrating the cortical and sclerenchyma layers, disintegrating them, and later breaking through the epidermis and forming black spore-producing bodies. This disease can be readily checked by the use of Bordeaux mixture.

The leaf anthracnose, caused by *Pestalozzia funerea*, made its appearance early in July, when black, velvety patches were observed at the bases of the leaves and flower stalks causing them to die and fall off. This form of anthracnose caused the death of thousands of young plants, and it was found that it also could be kept in check by spraying with Bordeaux mixture.

The wilt disease described is due to *Neocosmospora vasinfecta*, and this trouble has proved a very serious one, whole plantations often being destroyed in a single week. As the name suggests, the disease is to be recognized by the wilted appearance of the plants, and in this respect it greatly resembles the wilt of cotton, watermelon, and cowpeas. In fact, the fungus is considered identical with that causing the wilt of those plants.

The author investigated the entrance of the fungus through the roots, but a careful examination failed to show any signs of fungus infection. There was evidence, however, for believing that the fungus enters the plant at the base of the stem through the lesions caused by the stem anthracnose. This is shown from the facts that careful microscopical examination failed to reveal the presence of any fungi in the young parts of the roots, that where as a result of spraying there was no anthracnose fungus the plants were not affected by the wilt, and that the wilt disease never appeared until about 2 months after the stem anthracnose had made its appearance.

The fungus is not found except in the fibrovascular bundles while the plant is alive, while it is very customary to find the spore balls in the interior of dead, hollow stems, etc. The observations of the author have led to the conclusion that the wilt disease can be controlled by keeping the plants free from anthracnose and other fungi which produce lesions on the stems.

A technical account is given of the diseases and of the fungi causing them.

**A Phytophthora rot of apples, etc.**, A. OSTERWALDER (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 13-14, pp. 435, 440).—Following a severe rain and hailstorm in June, 1904, apples were found affected with an unusual rot. Upon investigation the cause was determined to be *Phytophthora omnivora*, and inoculation experiments showed the possibility of its causing the rotting of apples and pears within a relatively short time.

**Notes on the so-called roting canker of apple trees**, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 2, pp. 92-94, figs. 2).—The author describes an unusual form of apple-tree canker, in which the fungus stimulates the tree into the production of large knotty outgrowths. When sawed through, the perithecia of *Nectria ditissima* were found inside the knots.

**A bacterial disease of cherry trees**, R. ADERHOLD and W. RUHLAND (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 12, pp. 376, 377).—A preliminary note is given on a bacterial disease of cherry trees that has been quite destructive in some of the Rhine provinces of Germany.

This disease appears to have been hitherto confused with that described as due to the fungus *Valsa leucostoma* (E. S. R., 15, p. 270), but it lacks the characteristic outgrowth of that disease. The organism has been isolated and cultivated, and inoculation experiments show that it is capable of causing the trouble. The bacterium is described by the authors as *Bacillus spongiosus*. The disease is believed to be widely distributed throughout Germany. The authors intend further studies upon it, and suggest that it may also attack other stone and pomaceous fruit trees, as similar appearances have already been noticed on plum and apple trees in the vicinity of Dammkrug.

**Observations on the biology of the olive-tubercle organism**, E. F. SMITH (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 7-8, pp. 198-200, pl. 1).—The author was led to investigate the organism causing the olive knot (*Bacillus oleae*), to confirm statements by Schiff (E. S. R., 16, p. 987) relating to the biology of the bacillus.

The organism was isolated from olive knots from California, and studied under various conditions, comparisons being made with organisms plated out from material received from two different sources in Italy. In all of the material examined there

were found to be in addition to *B. olex* a number of other organisms. Successful inoculation experiments were made with the organisms from California and Italy.

The author failed to find resemblances between his bacteria and that described by Schiff, and he concludes that no olive knots can be produced with pure cultures of the spore-bearing organisms described by Schiff.

**Investigations on olive tuberculosis**, R. SCHIFF (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 7-8, pp. 200-211).—The results of the author's investigations on the cause of the olive tuberculosis and studies on the biology of the organism are given, a preliminary account of which has been noted elsewhere (E. S. R., 16, p. 987).

**The occurrence and prevention of gooseberry mildew**, R. EWERT (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 5, pp. 200-204).—Attention is called to the occurrence of *Glaosporium ribis* on gooseberries, the fungus causing serious injury to the plants.

An experiment in preventing the mildew was carried on in which the shrubs were sprayed with ordinary Bordeaux mixture, milk of lime, iron-free Bordeaux mixture, Bordeaux mixture to which varying proportions of iron sulphate were added, and soda Bordeaux. The shrubs were sprayed twice during the season, and the effect as shown on the bushes is described. The author recommends in general the spraying of the shrubs with a 1 per cent solution of ordinary Bordeaux mixture. He also recommends that resistant varieties, as far as possible, be planted, and that they be stimulated to rapid growth by means of cultivation and the use of fertilizers.

**The American mildew of gooseberries**, J. RITZEMA BOS (*Tijdschr. Plantenziekten*, 11 (1905), pp. 170-176).—Notes are given on the gooseberry mildew (*Sphaerotheca mors-uvæ*), which has recently appeared in a number of places in Europe, where it seems to be very destructive. The fungus and its effect on the host are described, and suggestions given for its prevention.

**Further investigations on the bacterial disease of sesame**, K. MALKOFF (*Ghoshishen Otchet Drzharnata Zeml. Opitna Stantziya Sadovo*, 2 (1904), pp. 149-156, [German Summary], pp. 14-19, pl. 5).—In continuation of a previous note (E. S. R., 16, p. 65) the author gives additional accounts of the biology of the organism causing the wilt of sesame.

The disease is still poorly known but may be recognized by the stems of badly infested plants being wilted and affected with a sort of black rot, while those less seriously attacked are checked in their growth and as a result the crop yield is considerably lowered. Repeated experiments in the isolation and cultivation of the organism and the results of inoculation experiments are described in detail. Field experiments showed that plants from early-sown seed seemed more subject to disease, and moist soils also favored its development. Treating the seed grain with a 0.1 per cent solution of formalin seemed to restrict the spread of the disease in some of the experiments.

**Concerning witches brooms of pear trees**, F. MUTH (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 2, pp. 64-76, figs. 11).—A description is given of witches brooms occurring on wild pear trees, the outgrowths being attributed to attacks of *Exoascus* sp.

**Witches brooms of *Quercus rubra***, SOLEREDER (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 1, pp. 17-23, fig. 1).—A description is given of witches brooms found upon the American red oak in a garden at Erlangen, Bavaria.

These growths have previously been reported as occurring on *Quercus ilex*, caused by the fungus *Exoascus kruchii*, and on *Q. lobata*, due to *E. quercus lobatae*, but the cause of the witches brooms on the red oak is thought to be an entirely distinct species of fungus from those mentioned above. A list is given of trees known to be subject to these growths and, so far as known, the fungi which cause them.

In a subsequent note, by K. von Tubeuf (same journal, No. 7, pp. 309, 310, figs. 2), the occurrence of these growths on red oak in other localities is mentioned.

**Witches brooms of fir trees**, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 6, pp. 253-260, figs. 5).—Illustrated descriptive notes are given on a number of forms of witches brooms observed on fir trees.

**Notes on *Thelephora laciniata***, K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), Nos. 2, pp. 91, 92, fig. 1; 4, pp. 187-189, figs. 3).—Brief accounts are given of attacks of *Thelephora laciniata* on young fir trees. The fungus, while not a true parasite, surrounds the lower parts of the seedling, ultimately causing its destruction. Very small seedlings are especially subject to attack. Moisture favors the development of the fungus. The seedlings should be thinned and stimulated by the use of fertilizers to make rapid growth. The same fungus is reported as injuring one-year-old beech seedlings.

**Further studies on *Melampsora* occurring on willows in Switzerland**, O. SCHNEIDER (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 7-8, pp. 232-234).—The results of inoculation experiments with *Melampsora ribesii-grandifoliae* and *M. larici-reticulata* are given, in which notes are presented on the teleutospore and Caoma stages of the fungi.

**The occurrence of timber dry rot in Russia**, L. VON LUBIMOFF (*Ztschr. Österr. Ingen. Architekt. Ver.*, 1905, p. 363; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 9, pp. 269, 270).—The rapid extension of railroad building, in which construction timber so largely enters, has served to call attention to the timber dry rot caused by *Merulius lacrymans*. The loss due to this fungus is said to be very great. To prevent its attack various preservatives have been employed, such as carbolineum, creosote, various tar oil and proprietary compounds, corrosive sublimate, etc., and notes are given on their use and relative efficiency.

**A sclerotium disease of Forsythia**, A. OSTERWALDER (*Ztschr. Pflanzenkrankh.*, 15 (1905), No. 6, pp. 321-329, pl. 1).—A description is given of a disease of the ornamental shrubs *Forsythia intermedia* and *F. suspensa* which is attributed to *Sclerotinia libertiana*, and the relation of certain conidia to the fungus is discussed. The stems, leaves, and flowers of the shrubs appear to be subject to attack of the fungus, which has proved quite destructive. The disease has been noticed for several years, but a careful search made in the spring of 1905 failed to show the wintering form of the fungus through the development of germinating sclerotia.

**The resistance of various varieties of roses to rust**, R. EWERT (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 6, pp. 249-252).—In 1903 investigations were begun at the Botanical Institute of Proskau on the rose rust due to *Phragmidium subcorticium*, and observations were made on the relative susceptibility of various classes and varieties of roses to the fungus, the observations being extended to cover the years 1903 and 1904.

Except in the hybrid perpetual class there was relatively little disease either year, and during 1904 there was much less than was observed the previous season. The meteorological data show that the rainfall from April to August in 1904 was only about one-third of the amount recorded in the previous year. The results of the observations are tabulated, from which it appears that the hybrid perpetuals as a class are more subject to attacks of *P. subcorticium* than any of the others studied.

**A competitive test of spraying apparatus**, J. RITZEMA BOS (*Tijdschr. Plantenziekten*, 11 (1905), pp. 81-96, pls. 2, figs. 8).—A report is given of the jury designated to award the prizes of the Pomological Society of Holland for hand, knapsack, and power sprayers. The jury in making its award took into consideration the size, weight, apparent durability, cost, relative efficiency, fineness of spray, etc. First and second prizes and honorable mention were awarded in each class.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Bark ringing by woodpeckers and its relation to forest insects,** G. FUCHS (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 8, pp. 317-341, pl. 1, figs. 7).—It has been shown by various authors that woodpeckers may attack healthy trees making a ring of punctures around the trunk and causing an outgrowth of a shelf-like structure at such points.

It appears that some of the species of woodpeckers are fond of the sap obtained in such outgrowths. It has also been observed that these ring structures may become infested with insects and are visited by woodpeckers in search of food. The author believes that on the whole woodpeckers are of more benefit in the destruction of injurious insects than harm as a result of injury to trees.

**The pine squirrel as a forest pest,** RUDOLF KOCH (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 7, pp. 298-303, fig. 1).—The author presents details regarding the nature of injury to the twigs of pines and fir trees by pine squirrels. The idea that these injuries are more often due to the attacks of *Garrulus glandarius* is without foundation.

**The loss of terminal twigs through the agency of pine squirrels,** K. VON TUBEUF (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 11, pp. 476-478, fig. 1).—According to observations made by the author all of the terminal twigs of pine trees eaten off by pine squirrels were subsequently replaced by lateral twigs which, however, grow considerably less rapidly than uninjured terminal twigs. The injury from pine squirrels is, therefore, considered as a serious matter.

**Cases of bark injury due to the pine squirrel (*Sciurus vulgaris*),** K. EPPNER (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 3, pp. 112-120, figs. 3).—According to the author's observations various species of pine are at times greatly injured by the pine squirrels gnawing off the bark and biting off the terminal branches. Several illustrations of this work of the pine squirrel are given which indicate that the injury from this squirrel may assume a serious character.

**The determination of generic types, and a list of roundworm genera, with their original and type species,** C. W. STILES and A. HASSALL (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 79, pp. 150).—Much confusion has prevailed in zoological literature on account of the uncertainty regarding scientific names and the authors believe that this is partly due to a failure to designate type species for genera at the time of their erection. The discussion presented in this bulletin is designed to prevent, as far as possible, further confusion.

A historical review is given of the principles of type designation, together with copies of the British Association Code, the Dall Code, the code of the American Ornithologists' Union, and of the German Zoological Society, as well as other rules proposed by the various individuals and associations. The principles maintained in the bulletin are illustrated by application to a list of genera of roundworms.

**The synonymy of *Tænia*, *T. crassicolis*, *T. marginata*, *T. serrata*, *T. cœnurus*, *T. serialis*, and *Echinococcus*,** C. W. STILES and E. C. STEVENSON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 80, pp. 14).—This bulletin contains a detailed synonymy of species contained in the subgenera *Tænia* and *Tæniarhynchus* as well as the species *socialis* in the genus *Multiceps*.

**International catalogue of scientific literature. N—Zoology** (*Internat. Cat. Sci. Lit.*, 3 (1905), pp. XI + 438).—The bibliographical references included in this volume are based mainly on literature published in 1903. It includes also certain articles published in 1901 and 1902. The bibliographical titles are grouped according to zoological classification.

**The fauna of British India including Ceylon and Burma. Butterflies, I,** C. T. BINGHAM (*London: Taylor & Francis, 1905, pp. XXII + 511, pls. 10, figs. 94*).—This volume is the first of a series of three which are being prepared by the author to

contain information regarding all the butterflies known to occur in British India. This work has been undertaken to supplement and complete that of de Nicéville. In the introduction to the volume the anatomy and classification of butterflies are briefly discussed. The families considered in this volume are Nymphalidæ and Nemeobidæ.

**Report of the entomologist**, C. P. GILLETTE (*Colorado Sta. Rpt. 1901, pp. 13-18, figs. 10*).—A summary is presented of the work thus far done at the station on codling moth. It appears that the eggs of the spring brood are deposited both on the fruit and leaves. Two applications of Paris green resulted in the saving of 25 to 90 per cent of the apples.

An examination has been made of a large number of bees with reference to the length of the tongue. The author has thus far been unable to find any evidence of a long-tongue race of Italian bees although several so-called long-tongue and red-clover bees have been examined. The length of the tongue in various races of bees ranges from 0.23 to 0.27 in. Brief notes are also given on sugar-beet insects and on a number of miscellaneous insects including Howard's scale, apple aphid, plum gouger, etc.

**Dangerous insects and diseases and their treatment**, L. R. TAFT (*Mich. Bd. Agr., Nursery and Orchard Insp. Bul. 1, pp. 16*).—The author briefly describes the purpose of the Michigan nursery and orchard inspection law and presents notes on San José scale, European fruit scale, scurfy scale, oyster-shell bark-louse, apple and peach aphid, cankerworm, crown gall, black knot, pear blight, peach yellows, little peach, and methods of fumigating nursery stock.

**Insect pests in West Australian orchards and vineyards**, F. LOWE (*Jour. Dept. Agr. West. Aust., 12 (1905), Nos. 4, pp. 302-307; 5, pp. 425-432*).—Attention is called to the climatic and other conditions which may exert an influence in determining the prevalence of insect pests and in affecting the relative abundance of parasitic insects. The subject of importation of parasitic insects is also discussed.

Particular attention is given to an account of the habits, life history, and means of combating the codling moth. In spraying for this insect the author recommends the use of Paris green at the rate of 1 oz. in 10 gal. of water to which 8 oz. of lime are added.

**A preliminary list of the more injurious insects of Texas, with notes on distribution** (*Texas Agr. and Statist. Rpt., 18 (1905), pp. 261-276*).—Some insect pests of the State are listed under the head of the plants which they affect.

**Entomological notes**, J. KOTINSKY (*Hawaii. Forester and Agr., 3 (1906), No. 1, pp. 8-11*).—Brief notes are given on the use of soap washes in the destruction of scale insects. A soap wash made in the proportion of 1 lb. of soap to 4 gal. of water has been used against the purple scale with satisfactory results in nearly all cases. Recommendations are also made regarding spraying apparatus.

**A yearly programme in entomological practice for the orchard**, H. A. GOSSARD (*Ohio Sta. Circ. 52, pp. 4*).—Recommendations are made regarding various insecticide operations to be applied in various months to apple, pear, quince, peach, plum, and cherry trees.

**Spraying calendar**, S. A. BEACH and E. E. LITTLE (*Iowa Sta. Bul. 85, pp. 39-53, figs. 2*).—In an introduction to this bulletin attention was called to the extent of damage caused by insects and fungus diseases in Iowa. The bulletin contains definite recommendations regarding the time for applying various insecticide and fungicide treatments and the materials and formulas to be used. The methods of preparing various spray mixtures are described.

**The mealie stalk borer**, C. W. MALLY (*Agr. Jour. Cape Good Hope, 27 (1905), No. 2, pp. 159-168, pl. 1*).—*Sesamia fusca* is a regular pest of corn in South Africa. The insect feeds upon corn, Kafir corn, and occasionally on other products. There appear to be only two well defined broods annually.

In controlling this pest it is recommended that old stalks should not be left in the field, but should be burned. In this manner the winter protection for the pest will be removed. Cornstalks may also be plowed under, but this is less effective, since they may not all be buried to a sufficient depth. Losses from the insect in question can not be materially reduced by late planting. A number of parasitic enemies are known, but they are not capable of reducing the number of the pest materially.

**The preservation of maize during transport by the Clayton process** (*Sci. Amer. Sup.*, 61 (1906), No. 1571, pp. 25177, 25178, figs. 10).—Brief notes are given on the various uses of corn and the methods of transporting it from one country to another. In such transportation maize may be attacked by beetles, and for destroying insect pests in corn sulphur fumigation by means of the Clayton apparatus has been found very efficient. The apparatus is suited to disinfection of dwelling houses and other buildings as well as ships. The apparatus in question distributes sulphur dioxide, sulphur trioxide, and other gases through the infested material, and destroys insects in such material.

**The control of micro-lepidoptera injurious to grapes in France**, J. DEWITZ (*Centbl. Bakt. [etc.]*, 2. Abt., 15 (1905), No. 15-16, pp. 449-467).—The most important micro-lepidoptera which attack grapes in France are *Tortrix pilleriana*; *T. ambiguella*, and *Eudemis botrana*.

In treating infested grapes in winter good results have been obtained from spraying with boiling water. Grapevines may also be sprayed with good results by the use of a mixture of lime, coal tar, caustic soda, and carbon bisulphid in water. Some of the insects in the winter stage may be destroyed by scraping the bark from grape trunks or by inclosing the trunks and fumigating with sulphur. Infested trunks may also be sprayed with a mixture of 10 kg. coal tar, 2 kg. oleic acid, 0.5 kg. caustic soda in 90 liters of water. In controlling these pests in summer some success has been had from the use of lantern traps, sticky substances, and various insecticides in weak solutions.

**Combating phylloxera in 1904**, D. CAVAZZA (*Ann. Uffic. Provi. Agr. Bologna*, 11 (1904), pp. 41-74).—A meeting was held in Imola at which measures were adopted regarding the control of phylloxera. As a result of this meeting measures were taken to determine the present status of infestation and the results of previous work in controlling the phylloxera. A committee was also appointed to study the distribution of American grape roots in the infested region and measures concerned with the control of the pest.

**The grape phylloxera in Hesse**, W. SCHUSTER (*Ber. Oberhess. Gesell. Nat. u. Heilk.*, 34 (1905), pp. 105-127, figs. 2).—A brief historical statement is given regarding the introduction of the grapevine phylloxera into Hesse and its subsequent distribution. Particular attention is given to a statistical account of the prevalence of this pest from 1878 to 1902.

**Natural enemies of the fruit fly**, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 27 (1905), Nos. 3, pp. 309-319; 4, pp. 457-469).—A visit was made to Brazil for the purpose of investigating fruit flies and their parasites with a view to the importation of possible beneficial parasites. The author and Mr. Fuller spent considerable time studying the conditions of the problem in localities where Mr. Compere had previously worked.

As a result of the investigations it is concluded that the efficiency of natural enemies of the fruit flies found in Brazil has been greatly overestimated by Mr. Compere. The fruit fly *Ceratitis capitata* is a serious pest in various parts of Brazil and appears not to be held in check by its natural enemies. Another serious fruit fly pest is *Anastrepha fratercula* and is also not greatly affected by natural parasites. The staphylinid beetle reported by Mr. Compere as an important enemy of the fruit fly was not found at all by the author.

**In search of parasites.** G. COMPERE (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 6, pp. 547, 548).—A short popular account is given of a recent visit to China in search of the parasites of red scale and purple scale and the announcement is made that in the near future an attempt will be put forth to secure parasites of the potato moth and woolly aphid.

**Some tree and wood-infesting insects.** Cabbage snakes, H. GARMAN (*Kentucky Sta. Bul.* 120, pp. 45-81, pls. 4, figs. 6).—The elm-leaf beetle has gradually spread over the eastern part of the State, where it has destroyed many neglected elms, particularly the imported species.

The use of bands about the trunks of elms is without effect in keeping the insects away from foliage, but sticky bands or other obstructions may be used for attracting the insects at the time of pupation. In one case more than 13,000 beetles were destroyed in this way about the base of a single tree. Just as effective work, however, may be accomplished by the use of scalding water or kerosene from time to time. The beetles on the foliage may be destroyed by the use of Paris green at the rate of 1 lb. per 100 gal. of water, together with 1 lb. of slaked lime or arsenate of lead at the rate of 3 to 4 lbs. per 100 gal. of water.

Notes are presented on insects affecting oak and other trees. Oaks are attacked by leaf miners and *Kermes pubescens*. The latter may be destroyed by spraying with lime-sulphur-salt wash. Brief accounts are presented of walnut worm, cottonwood leaf beetle, vagabond gall louse, poplar leaf tyer, willow leaf beetle, willow flea beetle, willow slug, apple-tree measuring worm, cicadas, June bugs, and other forest insects.

Considerable injury is reported to casks from the attacks of bark beetles, particularly *Monarthrum fuscicatum* and *M. mali*. The wood of vinegar barrels, beer kegs, wine casks, etc., was perforated by small holes which were most numerous near the hoops and at the joints between the staves. Since these insects bore into the wood in hope of finding fungus upon which to live, it is desirable to treat the casks so as to destroy the fungus. For this purpose Bordeaux mixture, copper sulphate, lime-sulphur wash, or bisulphite of lime are useful. The attack of the beetles is largely prevented by scalding the casks and treating them with lime.

On account of the unusual popular interest aroused in cabbage snakes, some attention was given to this subject. The term "cabbage snake" appears to have been applied to a slender species of *Mermis* which is parasitic in the bodies of a number of insects. In some localities the term has also been used for *Geophilus bipuncticeps*.

**The black locust tree and its despoliation.** C. A. WHITE (*Pop. Sci. Mo.*, 68 (1906), No. 3, pp. 211-218).—On account of the fact that the black locust is a rapidly growing tree it has recently been planted on an extensive scale for the production of railroad ties and for other purposes. The author believes, however, that on account of an attack of three especially injurious insects on the plantations, these trees are doomed to failure.

These pests are a leaf miner, gall insect, and the locust borer (*Cyllene robinia*). The last-named insect is the most injurious, burrowing through the trunk and larger branches, and rendering the wood unfit for use. Infestation by this pest is not observed at once; in fact the tree may be practically ruined for economic purposes without injury to the bark. The locust borer is exceedingly injurious wherever the black locust occurs in this country except in parts of California. Notes are given on the habits and life history of this pest and on possible remedies.

No effective remedies, however, have been devised. The application of repellent washes to the trunks of trees is suggested, but would be rather expensive.

**The root-louse of the Norway spruce.** A. JACOB (*Tharand. Forstl. Jahrb.*, 55 (1905), No. 3, pp. 177-197, pl. 1).—The habits and life history of *Rhizomorpha piceae* are described in considerable detail.

This insect appears on the roots of the Norway spruce, and, when present in large numbers, sucks the juice from the roots to such an extent that the trees are greatly weakened, or, in some cases, killed outright. In combating this pest, the best results have been obtained from the use of carbon bisulphid mixed with molasses and placed in the soil about the roots of infested trees. The molasses serves to hold the carbon bisulphid for some time, allowing it gradually to escape and produce its effect upon the insects. The insecticide may be injected into the soil by means of a syringe or placed in a furrow around the trunk.

**The number of annual generations among the bark beetles, E. KNOCH** (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), Nos. 9, pp. 353-368; 10, pp. 401-415).—The literature relating to the biology of various species of bark beetles is critically reviewed.

The author concludes from the study of literature and from his own observations that the question whether a given species of bark beetle produces 1 or 2 generations annually depends not so much upon the species as upon the temperature of the locality where the beetle is found. Nevertheless under given conditions different species do not vary in this respect, but each one shows the same number of generations from year to year.

**Tomiscus typographus**, O. NÜSSLIN (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), Nos. 11, pp. 450-468; 12, pp. 481-493, fig. 1).—This insect is described in its various stages with special notes on its occurrence in Herrenwies and Pfullendorf in 1905. In order to control this beetle it is very desirable that infested trees should be cut and removed from the forest before the beetles have emerged. This and the maintenance of trap trees are about the only practical remedies for the control of the pest.

**Pissodes harcyniæ**, G. FUCHS (*Naturw. Ztschr. Land u. Forstw.*, 3 (1905), No. 12, pp. 507, 508, pl. 1).—This insect is reported as occurring in large numbers in June on pine trees. As a result of the injury due to the beetle, infested trees became subsequently diseased through the attacks of *Trametes pini*.

**Lophyrus similis**, W. BAER (*Naturw. Ztschr. Land u. Forstw.*, 4 (1906), No. 2, pp. 84-92, figs. 3).—This sawfly is described with notes on some related species and on anatomical features which serve to distinguish it from the other species. Particular attention is given to the biological and morphological differences between *L. similis* and *L. pini*.

**Progress made in exterminating the fever tick in North Carolina, T. BUTLER** (*Raleigh: N. C. Dept. Agr.*, 1906, pp. 4, figs. 3).—The attention of cattle raisers is called to the fact that during the past 4 years 10 counties in North Carolina have been freed from cattle ticks and placed above the Federal quarantine line. The author considers that his experiments have demonstrated the feasibility of exterminating cattle ticks in all sections where stock laws prevail. It is believed that the ticks may be exterminated at a smaller cost than the annual loss due to cattle ticks in the affected regions.

**Fowl tick experiments, F. H. ROBERTSON** (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 6, pp. 561-563).—It was found that fowl ticks remain alive at least 2 years and 3 months without the presence of any fowls from which to derive nourishment. In these experiments the ticks were maintained in small pill boxes which were practically air tight. In the nymph stage ticks may live for 2 months without food.

**A classification of the mosquitoes of North and Middle America, D. W. COQUILLETT** (*U. S. Dept. Agr., Bur. Ent. Bul.* 11, tech. ser., pp. 31, fig. 1).—On account of the requests received by this Department from students of entomology, physicians, and sanitary officials regarding the identification of mosquitoes in various parts of the country, the present bulletin is prepared to furnish information along this line. The external anatomy of mosquitoes is briefly described, together with notes on the subfamilies, a table for identifying these subfamilies, and also analytical

tables for the identification of the genera and species of mosquitoes recognized in North and Middle America

**Household insects**, W. LOCHHEAD (*Canad. Ent.*, 38 (1906), No. 3, pp. 65-70, figs. 3).—Notes are given on the habits and life history of house flies, mosquitoes, fleas, bedbug, carpet beetles, clothes moths, larder beetles, mites in cheese, ham, and flour, flour beetles, meal worms, and red ants. Practical methods of combating these pests are suggested for each species.

**Report of the committee on apiary**, J. W. NELSON (*Ann. Rpt. Penn. Dept. Agr.*, 10 (1904), pp. 381-383).—The winter of 1904 is said to have been one of unusual severity for bees. Notes are given on the quality of honey obtained from various kinds of plants with particular reference to its color and taste. Attention is called to the desirability of a stringent law in Pennsylvania regarding the eradication of foul brood.

**Apiculture in Cuba**, E. W. HALSTEAD (*Estac. Cent. Agron. Cuba Circ.* 20, pp. 11, pls. 3, fig. 1).—Brief historical notes are given on the development of apiculture in Cuba, the management of bees, artificial swarming, introduction of queens, extraction of honey, foul brood, and other diseases of bees.

**Age at which bees first carry pollen**, C. C. MILLER (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 3, pp. 245, 246).—The difficulty experienced in determining this matter is considerably increased by the fact that bees so often attempt to rob honey from other colonies and in many instances become confused and enter the wrong hives. The author made a number of observations on this subject and will continue his investigations.

**Japan's three silk crops**, F. A. VIVANTI (*Yokohama: Japan Gazette Press*, 1905, pp. 10).—The great increase in the silk industry in Japan during the past 30 years is attributed by the author to the improved methods which have been adopted, so that three crops of silkworms may be fed annually.

Formerly sericulture was confined almost entirely to the northern provinces of Japan, but now this industry flourishes throughout the islands. The method by which the three crops of silkworms are fed annually is based on the use of cold storage. A large supply of eggs are placed in cold storage in the fall and carried over to the following spring. In May, when the first mulberry leaves appear, about 65 per cent of the eggs are taken out of cold storage and hatched. After about one month one-half of the remaining eggs are in turn taken out and hatched, thus producing the summer crop of cocoons which are ready for reeling in July or August. About a month later, the rest of the eggs are taken from cold storage and hatched, so as to produce the autumn, or third crop.

**Streptococcus bombycis in relation to emaciation and flaccidity of the silkworm**, S. SARTIRANA (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 40 (1905), No. 2, pp. 207-211; 40 (1906), No. 3, pp. 331-336).—The author studied the morphology and biology of this micro-organism with special reference to its connection with emaciation in silk worms.

As a result of numerous inoculation experiments, it is concluded that the micro-organism in question must be considered as the only specific cause of this disease. It is found chiefly in the alimentary tract, and causes local lesions, which lead to chronic enteritis. Flaccidity, however, can not be considered as a peculiar disease caused by one micro-organism alone; it is rather a mixed infection due to a number of micro-organisms, including streptococci.

## FOODS—HUMAN NUTRITION.

**Food and diet in health and disease**, R. F. WILLIAMS (*Philadelphia and New York: Lea Bros. & Co., 1906, pp. X+392, fig. 1*).—This volume, which is designed as a text-book for students, has two main divisions, the first treating of food in health and the second of food in disease.

Available data are summarized regarding the chemistry of foods, the physiology of digestion, the changes brought about by cookery, the characteristics of different food groups, feeding in infancy and old age, as well as special diets suited to different diseases, preparation of foods for invalids, and related questions, the volume as a whole constituting a concise summary of the subject of nutrition from the physician's standpoint.

In his introduction the author states that the first half of the volume, which deals with nutrition and food in health, is largely based on the results of the nutrition investigations which have been carried on under the auspices of the Office of Experiment Stations.

**A new method of indicating food values**, I. FISHER (*Amer. Jour. Physiol., 15 (1906), No. 5, pp. 417-432, figs. 23*).—A system of expressing the nutritive value of food is described in which a quantity yielding 100 calories is selected as the basis for comparison. The author believes that this gives a better idea of the relative nutritive value of different foods than the usual method of expressing percentage composition.

A method is described in which a right-angled triangle is divided in such a way that composition is expressed graphically. The author has devised an instrument by which the nutritive value of a food or diet may be estimated according to his system.

**An inquiry into the extent of underfeeding amongst the school children of Blackburn**, A. GREENWOOD (*Blackburn, Eng.: Times Printing Works, 1905, pp. 76*).—From a careful study of the existing conditions it is stated that probably not more than 1.3 per cent of the Blackburn school children are underfed. The author believes that "considerable waste occurs in many homes through a lack of knowledge as to cheap nutritious articles of diet and economical cooking. . . . It is important that the elder girl scholars should be taught the preparation and cooking of such meals as are available in a workingman's home."

**The function of cellulose in the diet of man**, I. H. LOHRISCH (*Zschr. Physiol. Chem., 47 (1906), No. 2-3, pp. 200-252*).—A large amount of experimental data is reported on the digestibility of cellulose supplied by a number of common food materials.

The results obtained showed that with normal digestive apparatus cellulose is more or less well digested, and indeed under some circumstances is thoroughly digested, the thoroughness of digestion being indirectly proportional to its hardness. On an average the normal subjects studied by the author digested 57.9 per cent of the cellulose, patients suffering from chronic constipation 81.4 per cent, and those suffering from other diseases amounts to considerably less than normal.

The question of cellulose digestion, the author believes, will not be understood until the ferments inducing it, at present unknown, are identified and studied. The article contains a review of earlier investigations and a bibliography.

**The influence of the dietary on the constituents of the urine**, A. DESGREZ and J. AYRIGNAC (*Compt. Rend. Soc. Biol. [Paris], 60 (1906), No. 13, pp. 616-618*).—The proportion of different constituents of the urine and their relation to each other was studied on an absolute and mixed milk diet, milk and egg diet, vegetarian diet, and mixed diets containing large and small amounts of meat.

The ratio of nitrogen of urea and total nitrogen reached its minimum in the vegetarian diet and its maximum in the absolute milk diet. The ratio of uric acid to urea was greatest on a vegetarian diet and least on a mixed diet containing large

amounts of meat. The phosphoric acid and sulphur constituents of urine were also studied.

**The effect on metabolism of overfeeding protein**, M. SCHREUER (*Arch. Physiol. [Pflüger]*, 110 (1905), No. 3-4, pp. 227-253).—The investigations showed that feeding large quantities of protein did not permanently increase the protein content of the body. An increased oxygen consumption was noticed in experiments with dogs when large amounts of protein were taken, which indicated an increased cell activity, but this increase in the material stored in body cells was not found to be permanent.

**Protein feeding and the estimation of glycogen**, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 111 (1906), No. 7-8, pp. 303-308).—For exact estimations of glycogen the author insists that his cuprous-oxid method should be used.

**Some considerations on proteid diet**, L. F. BARKER and B. A. COHOB (*Jour. Biol. Chem.*, 1 (1906), No. 2-3, pp. 229-238).—Using Hausmann's method, the amid, melanoidin, diamino, and monamino nitrogen was determined in veal cutlet, pork chop, beef sirloin, beef tenderloin, beef neck, heart, liver, thymus, chicken, and trout, with a view to determining something regarding composition and differences in food value. The various forms of nitrogen were rather evenly distributed in the foods analyzed.

**The chemistry of flesh, IV. A study of the proteids of beef flesh**, P. F. THOWBRIDGE and H. S. GRINDLEY (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 4, pp. 469-505).—The conclusions drawn from an extended chemical study of the proteids of beef flesh were in effect as follows:

The total acidity of aqueous extracts of flesh varies between comparatively wide limits, the minimum being 0.66 per cent, the maximum 1.07 per cent, and the average 0.85 per cent, calculated as lactic acid and expressed in terms of the fresh substance of the meat. The residues of flesh which are left after the complete extraction with cold water are distinctly acid to litmus and to phenolphthalein. On the other hand, the insoluble proteids of flesh upon digestion with decinormal hydrochloric acid at ordinary temperature combine with it and neutralize its acid properties.

Analyses made by the authors show that 13.56 per cent of the total proteid existing in lean beef flesh is soluble in cold water. Of this total soluble proteid 90.04 per cent is in a form which is coagulable by heat from a neutral solution, 8.40 per cent exists as albumoses and a very small quantity apparently exists in the form of peptones. Presumably, the albumoses and peptones do not exist as such in the original flesh. During the coagulation of an aqueous extract of flesh there is an increase in its acidity. Reduction of the acidity of aqueous extracts of flesh facilitates coagulation of the proteids.

There are no well-defined degrees of temperature at which different coagula of aqueous extracts of flesh separate. The complete removal of the proteid coagulating at any fixed definite temperature requires long application of heat. Further, the lower the temperature at which a coagulum is separated, the longer the time of heating required to effect complete coagulation.

The chemical composition of the different fractional coagula of the aqueous extracts of raw flesh is remarkably constant. They are also quite similar as regards their chemical constitution judging from the results of their hydrolysis.

Raw flesh which has been completely freed from proteids soluble in cold water contains two classes of proteid substances, those which are soluble in a 10 per cent solution of ammonium sulphate and those which are insoluble in this medium.

For earlier work see E. S. R., 17, p. 886.

**The globulin of muscle fibers**, L. MOROSHOWETZ (*Physiol. Russe*, 4 (1905), No. 61-67, pp. 42-52).—A historical account is given of the globulin of lean meat (myoglobin), the chemistry of the subject, and related questions, and the results of studies of preparation, characteristics, and properties reported. According to the author,

if repeatedly dissolved in ammonium-sulphate solution and precipitated with this or some other salt a product is finally obtained which, after dialysis, contains only an inappreciable quantity of ash.

**The globulin of egg yolk**, I. MOROCHOWETZ (*Physiol. Russe*, 4 (1905), No. 61-67, pp. 53-59, fig. 1).—Historical and other data are summarized regarding globulin of egg yolk (vitelloglobin) and studies of its preparation and properties reported. When free from fat and other contaminating bodies, this globulin did not differ from other globulins in respect to its solubility in a solution of common salt or other salts.

**The liver as a storehouse for protein**, W. SEITZ (*Arch. Physiol. [Pflüger]*, 111 (1906), No. 7-8, pp. 309-334).—In experiments with chickens the conclusion was reached that protein is stored in the liver.

**The effect of constituents of low-grade flour on the extraction of gluten and upon bread-making properties**, LINDET and L. AMMANN (*Ann. Chim. Analyt.*, 10 (1905), No. 12, pp. 454-456; 16-17, pp. 1005-1014).—The difficulty experienced in extracting gluten of low-grade flour, according to the investigations reported, is due to its acidity and to the presence of a mucilaginous substance and of small carbohydrate particles derived from the bran, which become mixed with the gluten particles and prevent agglutination. To facilitate the determination of gluten this bran material should be removed by the action of ferments and the acid and mucilaginous material by extraction with water.

In the second paper, which gives a more extended account of the investigations, the authors conclude that glutenin is made up of fine particles which are not very coherent embedded in a mass of gliadin which imparts the agglutinating properties. The effect of heating at different temperatures and related questions are considered.

**The acidity of bread and its causes**, H. STIEGLER (*Pure Products*, 2 (1906), No. 4, pp. 183-186).—The acid reaction of bread is due either to free organic acid or to acid potassium phosphate. The formation of acid in flour and leaven, as pointed out, must be attributed to micro-organisms and particularly to bacteria, and a number of sorts of bacteria which produce acid in bread are described.

"When pure yeast is employed in the preparation of the bread, the product exhibits a low acidity; the dough is then so rapidly raised by the growth of the yeast cells and of their fermenting power, that the acid-forming bacteria have no chance to develop. This is the case also with rye bread, whose normally rather high acidity is not derived from the flour. It is the use of impure yeasts, of sour milk and of rancid butter which produces the high acidity in bread leavened with yeast. The acids of bread do not appear to lower its nutritive value, yet a very sour bread will interfere with the digestion of many persons."

**The nutritive value of Corsican chestnut flour**, P. COMTE (*Jour. Pharm. et Chim.*, 6. ser., 22 (1905), No. 5, pp. 200-210, fig. 1).—Composition, characteristics, and microscopical structure of Corsican chestnut flour are considered, as well as its nutritive value and place in the diet. According to analyses it contains somewhat less protein and somewhat more nitrogen-free extract than wheat flour. The author considers it a palatable and valuable food product.

**Study of apple marc**, W. D. BIGELOW and H. C. GORE (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 2, pp. 200-207).—The data reported show that the hot-water extract, constituting 40 per cent of apple marc, consists of one carbohydrate complex, a galacto-araban.

"The carbohydrate complexes in case of the alcohol precipitate of apple must, and in case of the alcohol precipitate of second pressing ciders, are both higher in galactan, relative to the pentosan content, than the hot-water extracts of apple marc. The treatment with boiling water lessens the yield of crude fiber and cellulose, and at the same time gives a purer fiber and a purer cellulose." (See also E. S. R., 17, p. 465.)

**Changes in the composition of the fruit of cucurbits**, LÉCIÈRE DU SABLON (*Compt. Rend. Acad. Sci. [Paris]*, 140 (1905), pp. 320, 321).—The sugar, starch, and

water content of different sorts of cucurbit fruits was determined before, during, and after maturity. The sugar, which was abundant in the unripe fruit, diminished during the ripening processes, increased after the fruit was ripe and again diminished. The starch content increased until the fruit was harvested and then diminished, while the water content first increased, then diminished markedly at maturity, and afterwards increased.

**The chemistry of celery (*Apium graveolens*),** I. M. BAMBERGER and A. LANDSIEDL (*Monatsh. Chem.*, 25 (1904), pp. 1030-1034; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 10 (1905), No. 10, p. 619).—In the roots of tuberous rooted celery the authors report 0.48 per cent asparagin, and a smaller amount of tyrosin in addition to mannit. Leucin was not found.

**The absorption of sulphurous acid from the air by meat,** A. KICKTON (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 6, pp. 324-328).—The experiments showed that when sulphurous acid was present in air meat would absorb it, the surface containing considerably more than the interior.

**Evaporated cream** (*Mo. Bul. Bd. Health Mass.*, n. ser., 1 (1906), No. 3, p. 61).—Determinations of fat showed that so-called evaporated creams were merely unsweetened condensed milks, having somewhat the consistency and appearance but neither the taste nor physical characteristics of cream.

**The artificial coloring of mustard,** P. KOPCKE (*Pharm. Centralhalle*, 46 (1905), p. 293; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 6, pp. 349, 350).—The method of detection suggested depends upon the extraction of the coloring matter with ammonia and showing the presence of artificial coloring matter by dyeing a sample of woolen goods.

**Honey vinegar,** J. J. HOFMANN (*Pharm. Weekbl.*, 42 (1905), pp. 704, 705; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 6, p. 356).—Honey vinegar is manufactured on a commercial scale in Holland. A number of samples were examined and found to possess an agreeable aroma and taste.

**Report of work in the food and drug laboratory,** H. E. BARNARD and J. N. HURRY (*Mo. Bul. Ind. Bd. Health*, 7 (1905), No. 11, pp. 130-144; 8 (1906), No. 1, pp. 5-21).—Over 50 per cent of the foods, condiments, and beverages examined under the provisions of the State pure food laws were found to be adulterated.

**The pure food and drug laws of the State of Indiana** (*Mo. Bul. Ind. Bd. Health*, 7 (1905), Nos. 7, pp. 75-88; 8, p. 95).—The legislative enactments regarding pure food and drugs in the State of Indiana and the food and drug rules of the State Board of Health are quoted.

**The pure food law in Germany, its origin and growth, and its effect upon the commercial food industry and upon diet,** A. JUCKENACK (*Deut. Vrtjsschr. Öffentl. Gesundheitspflege*, 57 (1905), pp. 678-688; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 11 (1906), No. 6, pp. 353, 359).—The growth, development, and results of the German pure food law are discussed. In the author's opinion this law is responsible for a great improvement in the quality of food products and in food considered from a sanitary standpoint.

## ANIMAL PRODUCTION.

**The composition of some Hawaiian feeding stuffs,** E. C. SHOREY (*Hawaii Sta. Bul.* 13, pp. 23).—Proximate and ash analyses are reported of a number of samples of sorghum, sugar cane tops, millet, Kafir corn, wild and cultivated grasses, alfalfa, wild cowpea, cowpea, 2 sorts of *Desmodium*, pigweed, sow thistle, *Commelina nudiflora*, *Bidens pilosa*, prickly pear, *Acacia farnesiana*, banana tops and butts, taro tops, sweet potato tops, ti leaves (*Cordyline terminalis*), cassava roots, brewers' grains, molasseuit, algeroba beans (whole beans—pods and seeds), rice bran, rice polish, and cocoanut meal. In addition to the usual constituents the percentage of total, proteid, and amid nitrogen was determined.

A fact of special interest brought out by the bulletin is that a number of Hawaiian feeding stuffs, particularly those belonging to the grass family, are deficient in lime, and that the failure to obtain the best results, which has sometimes been noticed with a ration which was apparently well balanced, may be attributed to this cause. In order to secure the best results in bone development, health, etc., the author believes that such feeding stuffs should be supplemented by others richer in lime, as leguminous plants, algeroba beans, and sugarhouse by-products, or by the use of more lime either in the drinking water, mixed with the feeds used, or applied to the soils producing the forage crops.

"While the analyses reported in this bulletin are not considered sufficiently numerous to warrant any extended comparison of Hawaiian feeding stuffs with one another or with those of other regions, or to justify elaborate discussion of the best ways of utilizing the various feeding stuffs in Hawaiian practice, they do show that the Hawaiian feeder has at his command a quite large and varied assortment of feeding stuffs, many of which are of high nutritive value, and it is believed that the information given in the bulletin will aid the feeder in selecting from the feeding stuffs available those which will give him the cheapest and most efficient rations for his stock."

**Analysis of fodder plants**, E. A. MANN (*Jour. Dept. Agr. West. Aust.*, 13 (1906), No. 2, pp. 142-145).—Among the plants analyzed were black boy leaves, grass tree leaves, African wonder grass, and *Eragrostis pilosa*.

**Feeding stuff inspection**, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 129, pp. 81-100).—Under the State feeding stuff law analyses were made of a number of samples of cotton-seed meal, cotton-seed feed, linseed meal, viscid oil meal, gluten meals and feeds, distillers' grains, molasses feeds, mixed and proprietary feeds, corn meal, hominy meal, wheat bran, wheat middlings, mixed wheat feed, oats, beef scrap, and similar goods.

With the exception of samples of cotton-seed meal submitted by jobbers for the purpose of learning their quality, the authors state that they found no cotton-seed meal which was below the Cotton-seed Crushers' Association standard for prime goods.

**Inspection of concentrates**, J. B. LINDSEY ET AL. (*Massachusetts Sta. Bul.* 108, pp. 51).—The concentrated feeds analyzed under the State law include blood meal, cotton-seed meal, linseed meal, oil meal, viscid oil meal, gluten meal and feed, brewers' and distillers' dried grains, malt sprouts, wheat middlings, mixed wheat feeds, wheat bran, dairy feeds, sugar feeds, rye feeds, buckwheat feeds, calf meal, corn meal, hominy meal, provender, corn and oat feeds, oat feeds, dried beet pulp, corn bran and similar goods, cereal breakfast food by-products, meat scraps and similar goods, dried fish, granulated milk, poultry feeds, and alfalfa and clover meals.

The various corn and oat feeds, the authors state, may be divided into two classes, namely, those consisting largely of oat refuse with some corn, frequently of low quality, and occasionally a little red dog middlings, and those consisting principally of hominy, to which has been added more or less oat offal. The feeding stuffs included in the first class have a rancid, bitter taste, while those in the second group are generally sweet and more attractive. Such goods are inferior to clean, bright corn or hominy meal, yet, as the authors point out, they cost nearly or quite as much.

"Alfalfa [meals], as well as clover meals, are now obtainable for winter feeding. The former should carry 18 per cent protein, and the latter 12 per cent. Preference should be given to bright, clean lots, free from excess of coarse, woody stalks. The price (\$1.80 a hundred) is rather in excess of their value. Poultrymen, by raising corn and clover, can considerably reduce their outlay for food. . . .

"Molasses may constitute one-sixth to one-fourth of the grain ration for horses (one pint to one quart daily). A larger quantity tends to make them logy. The same amount may be fed daily as a constituent of the grain ration for dairy stock."

**The inspection of feeding stuffs in 1905**, F. W. MORSE (*New Hampshire Sta. Bul.* 124, pp. 147-152).—Analyses are reported of 84 samples of cotton-seed meal, linseed meal, gluten meal, gluten feed, distillers' grains, hominy feed, compounded cattle foods, vegetable poultry foods, animal meal and similar poultry foods, and bone meal.

The following statements are quoted from the discussion of the analytical data:

"There were found to be 3 distinct classes of cotton-seed meal, according to the percentage of protein, being guaranteed, respectively, to contain 38.5 per cent, 41 per cent, and 43 per cent. . . . The prices were practically alike for all three grades. This is an injustice to the consumer because the lowest grade contains more lint and hulls than the highest grade. The consumer, however, can protect himself by reading the tags on the sacks. . . . Two brands of so-called mixed feed were collected, which were not pure wheat products. One contained corn cob and gave an exceptionally high fiber, while the other was made up largely of screenings, finely ground. They complied with the law in bearing proper labels, but one was inferior to its stated composition. . . .

"There are no failures on the part of any of the poultry foods to reach the percentage guaranteed, while some of the animal meats and scraps overrun heavily, especially in fat. Excessive amounts of fat would not seem advantageous for laying hens, however."

**Licensed concentrated feeding stuffs**, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul.* 134, pp. 17-23, 27-30).—A list of the feeding stuffs licensed for sale during the calendar year 1906 is given, together with the guaranty of their protein and fat content. The text of the State feeding stuff law is quoted.

**The nutritive value of the nonprotein nitrogen compounds in feeding stuffs**, E. SCHULZE (*Jour. Landw.*, 54 (1906), No. 1, pp. 65-81).—A summary and discussion of available information concerning the nonprotein constituents of feeding stuffs. The author considers that many of these constituents possess considerable nutritive value, while others are of little or no importance in nutrition. In the latter group, asparagin and perhaps glutamin are included.

**Experiments on the value of asparagin and lactic acid in the feeding of Herbivora**, O. KELLNER (*Verhandl. Gesell. Deut. Naturf. u. Aerzte*, 76 (1904), II, 1. Abt., p. 145; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 1, pp. 45-48).—From experiments with sheep the conclusion was reached that neither asparagin nor lactic acid bore any part in the gains which were made. The author believes that asparagin has a value in that it tends to prevent the lowering of digestion noted with a very low protein diet and so acts indirectly and in a limited way as a protector of protein.

**Digestion experiments with forage plants**, H. G. KNIGHT (*Wyoming Sta. Rpt.* 1905, pp. 52-60).—Experiments on the digestibility of alfalfa hay by sheep gave the following average coefficients: Dry matter, 63.39; protein, 79.67; fat, 41.20; ether extract, 74.08; crude fiber, 44.84, and ash, 56.17 per cent.

**Feeding beef cattle in Mississippi**, A. SMITH and C. I. BRAY (*Mississippi Sta. Bul.* 92, pp. 24, figs. 10).—To study the relative merits of feeding in a warm stable and an open yard and to compare a mixed ration of hay and grain with one of cotton-seed meal and hulls only, a feeding test was undertaken with 5 lots of steers. Three of the lots were made up of 5 animals, one of the lots of 7, and one of 3 animals. The cattle in the latter lot were scrubs and the others thrifty animals and medium feeders. Three of the lots were fed in a stable and two in yards, one with and one without an open shed for shelter, the mixed ration and the cotton-seed meal and hull ration being so arranged that each was tested under the 2 conditions of feeding. The test covered approximately 14 weeks.

Considering the thrifty animals fed in stalls the average gain on the mixed ration was 201 lbs. per steer and on the ration made up of cotton-seed products 185 lbs. per steer, the cost of a pound of gain in the 2 cases being 8.5 cts. and 6.1 cts. The scrub

steers fed in a stall made an average gain of 130 lbs. at a cost of 10.7 cts. per pound. The steers fed the mixed ration in a yard gained on an average 196 lbs. at a cost of 9.13 cts., and the similar lot fed the ration of cotton-seed products gained 146 lbs. at a cost of 8.2 cts.

The manure may be more readily saved when the steers are fed in stalls. Its estimated value in the test reported was \$80.

Following are some of the authors' conclusions:

"The comparison between the stable versus open yard system while showing some advantage in favor of the stable method really indicates that a combination of the best features of both systems is preferable. This could be done by allowing the cattle to run in large sheds with a solid tight floor which should be well bedded, and the manure all saved. If desired, outside yards connected with these sheds could be provided, so that the cattle could have some exercise and plenty of fresh air. One of the secrets of successful cattle feeding is in making them as comfortable as possible.

"Where cotton-seed meal and hulls can be purchased at a reasonable price, they prove to be very cheap feeds for fattening steers. No bad effects result from feeding cotton-seed meal for such short periods as this, and it remains to be seen whether any ration can be compounded exclusive of good silage, which can equal it as an inexpensive feed.

"Dairy farming has many points of superiority over beef raising, but to farmers who are not close to a good market and are handicapped by lack of available and steady labor, the breeding and feeding of cattle will offer many inducements. That it is a profitable business in the South is shown by the low cost of raising cattle, economy in producing suitable feeds, and the inexpensive buildings required. With a good pure-bred beef sire, a herd of native cows, and plenty of pasture land, a farmer may in 2 or 3 years' time develop a good grade beef herd, which will largely increase his profits and maintain the fertility of the soil."

**Summary of swine feeding, 1904-5, G. E. MORTON (Wyoming Sta. Rpt. 1905, pp. 44-47).**—Many believe that corn is necessary for pork production, and a comparison of wheat and corn was made with 2 lots of 3 pigs each. In 11 weeks the total gain on wheat was 342 lbs. and on corn 229 lbs.

In a second test wheat and alfalfa hay with and without roots were studied with 2 lots of 2 pigs each. In 13 weeks the lot fed roots gained 183 lbs. and the lot without roots 185 lbs. "Evidently the roots fed did no good in anyway; they were simply an additional expense."

Judging by both tests "straight wheat feeding gives the best gains of any of the rations tabulated, but it also involves very heavy grain feeding [8 to 24 lbs. per day at the end of the test] to get the gain."

"An answer to the question whether this extra gain and less amount of concentrates is offset by the cost of the alfalfa hay depends upon the comparative cost of the feeds in a given locality."

A sow weighing 341 lbs. was fed for 14 weeks beginning December 3, alfalfa hay and roots only, consuming on an average 6 lbs. of the hay and 6 to 24 lbs. of the roots per day. At the end of the period she had lost 7 lbs.

Three sows fed corn, shorts, and alfalfa hay gained 122 lbs. in 6 weeks. "The gain shown . . . is good and the sows were apparently put in good condition for pigging by this ration. One sow gave birth to 7 living pigs and 1 dead pig, the other gave birth to 5 living and 3 dead. Further experimentation will be required to determine whether the ration was responsible for the stillbirths."

Corn and shorts, corn and alfalfa hay, and wheat and corn each with alfalfa hay chopped in swill were compared with 4 lots of 3 pigs each, averaging 65 lbs. each in weight. The gain on corn and shorts 1.2 was 61 lbs., and on corn and alfalfa 1:2, 19 lbs. On each of the rations made up of grain, alfalfa hay, and swill there was a loss

of 3 lbs. "The alfalfa rations for young growing pigs were lamentable failures. The pigs grew scrawny and lost weight."

**Supplements to corn for fattening hogs,** F. B. FORBES (*Missouri Sta. Bul.* 67, pp. 19).—Using 15 lots of 4 or 5 pigs each concentrated feeds in varying proportions and combinations were compared as supplements to corn meal for dry-lot fattening. Ear corn was also compared with corn meal, both being fed with linseed oil cake.

The tests were made in the winter and covered 29 to 90 days, being preceded by preliminary periods of 4 to 6 weeks. The pigs were confined in small pens with a shed, but were not protected from wind and cold. The grains were ground and mixed to a slop with water except in the comparison of ear corn and ground corn.

When corn meal was supplemented by wheat middlings and linseed meal with and without germ oil meal and gluten meal and feed for 90 days, the gain ranged from 0.971 lb. per head per day on corn meal and wheat middlings 2:1 to 1.430 lbs. on corn meal and linseed meal 5:1, and the grain eaten per pound of gain from 4.45 lbs. on the latter ration to 5.18 lbs. on the former.

When linseed meal and wheat middlings were compared in varying proportions as supplements to corn meal in short periods (29 to 45 days) both the smallest and greatest gains, 1.269 and 1.776 lbs. per head per day, were noted with lots fed corn meal and linseed meal 5:1. The grain required per pound of gain was least with one of these lots being 3.85 lbs. and greatest, 4.75 lbs., with a lot fed corn meal and wheat middlings 2:1.

"The rations of linseed oil meal and corn meal in proportion of 1:5 were eaten in large quantity than any other feeds tested and made more pork with smaller expenditure of feed than any other ration involved."

The estimated cost of pork made from the oil-meal rations averaged 11.3 per cent less than from the rations of corn meal and wheat middlings.

"Of the three corn products, gluten feed, gluten meal and germ oil meal, the first mentioned seems to be more useful than the others when fed with corn and linseed oil meal. None of them, however, in this combination are as useful as linseed oil meal by itself.

"(Gluten meal is richer than gluten feed, differing from it only in lacking the corn bran with which it is ground to make the latter, but it does not seem to be as useful a supplement to corn and oil meal. The ration containing it was not so well relished and was not so efficient. It is possible that the usual recommendation that gluten meal be soaked before feeding to hogs would, if followed, have rendered it more valuable in comparison with gluten feed than it was in this experiment where it was fed immediately after wetting."

In 3 of the tests a mixture of corn meal and cotton-seed meal 8:1 was fed for 51 days. Cotton-seed meal fresh from the factory was fermented at living room temperature for 24 hours previous to feeding, sour milk being used as a starter. It was hoped that this fermentation would render the meal less toxic than it is reputed to be. The cotton-seed meal ration was mixed to a thinner slop than the other rations as it has been claimed that this is a desirable practice. The average daily gain per pig was 0.966 lb. and the grain eaten per pound of gain 4.97 lbs. Three of the 15 pigs included in these tests died at the end of the feeding period. "The gains up to that time had been moderate in extent and cost. The hogs did not relish this feed. A change to the corn and linseed oil meal ration induced much greater consumption of grain, increased the gains in weight 39 per cent and reduced the grain requirement per pound of increase to the extent of 13.1 per cent."

When ear corn and linseed cake 6:1 were compared with corn meal and linseed cake 5:1, the average daily gain per pig on ear corn during the 61 days of the test was 1.004 lbs. and the grain eaten per pound of gain 6.65 lbs. Similar values for the corn meal ration were 1.291 lbs. and 6.05 lbs.

Corn meal and oil cake "fed dry and mixed produced gains in weight with 9 per cent less grain than did ear corn and oil cake fed separately, both dry. The gain in the corn meal lot was 28.6 per cent greater than in the ear corn lot. The hogs receiving ear corn would not eat more than one-sixth as much oil cake as corn (the cob figured out) when both were allowed ad libitum."

In the opinion of the author the severity of the weather had an unfavorable effect on the gains made. The subject is discussed and data summarized regarding the influence of temperature on gains, indicating "that extreme heat of summer and extreme cold of winter act alike to the extent that they both occasion large energy expenditure on the part of the animal, in one case to keep warm, in the other to keep cool; and in either case occasion a great reduction in the profit from feeding in the dry lot when compared with results obtained in spring and fall. These results, however, do not apply to the feeding of hogs on pasture."

**The poultry industry in Tasmania**, R. J. TERRY (*Agr. and Stock Dept. Tasmania, Bul. 7, pp. 15, figs. 4*).—Various questions connected with profitable poultry raising under local conditions are discussed and some experimental data on fattening poultry are briefly reported.

### DAIRY FARMING—DAIRYING—AGROTECHNY.

**Profitable dairying**, C. L. PECK (*New York: Orange Judd Co., 1906, pp. XII + 174, figs. 34*).—This is offered as "a practical guide to successful dairy management," and consists of 23 chapters in which are discussed the physiology of milk secretion, dairy breeds, feeding cows, milking, care of milk, butter making, and similar topics.

**Breed, individuality, and heredity in the production of milk**, M. FISCHER (*Landw. Jahrb., 35 (1906), No. 3, pp. 333-379, pls. 3*).—A study was made of the yield and composition of the milk with particular reference to the casein of 12 cows representing 6 different breeds, and also of 10 cows selected from a large herd with a view to showing the influence of individual characteristics and heredity.

The milk of the mountain breeds including the Brown Swiss and Simmental showed a higher percentage of fat, casein, and solids-not-fat than that of the lowland breeds including the Oldenburg, East Friesian, Angler, and Wilstermarsch. The average annual yield of the latter group, however, was greater, making the annual yield of fat and casein of the 2 groups practically the same. In producing milk for cheese making the Brown Swiss breed is considered especially valuable as compared with the other breeds mentioned.

Within the same breed the author finds in casein production as in fat production marked individual variations. The transmission of individual characteristics is discussed at some length.

**A test of a fly repellent**, C. H. ECKLES (*Missouri Sta. Bul. 68, pp. 35-39*).—The entire dairy herd was sprayed with a fly repellent each morning during alternate periods of 2 weeks each. The test was continued during the entire summer of 1903 and for 6 weeks in the summer of 1904. The yields of milk and fat during the periods when sprayed and when not sprayed are tabulated and show no important effects either upon the yield of milk or fat due to the use of the fly repellent. When applied every morning the material used was fairly effective in protecting the cows from flies, but the claim made that the material will protect cows if applied at intervals of several days is considered erroneous.

**Milking machines**, P. G. WICKEN (*Jour. Dept. Agr. West. Aust., 13 (1906), No. 4, pp. 301-303, pls. 2*).—This is a summary of a report on the use of milking machines in Western Australia, the author concluding that the Lawrence-Kennedy-Gillies machine is now beyond the experimental stage and is working in hundreds of places daily giving practical results.

**The composition of milk**, H. D. RICHMOND (*Analyst, 31 (1906), No. 363, pp. 176-180*).—The average composition of 14,828 samples of milk analyzed during 1905

was as follows: Specific gravity, 1.0323; total solids, 12.70 per cent; fat, 3.73 per cent; and solids-not-fat, 8.97 per cent. The average fat content of the morning milk was 3.54 per cent and of the evening milk 3.91 per cent.

Analyses are also reported of 1 sample each of human milk, ass's milk, adulterated cream, a butter adulterant, and a new preservative. The butter adulterant consisted mainly of casein and the new preservative was acid potassium fluorid.

**The milk supply of Boston, New York, and Philadelphia,** G. M. WHITAKER (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 81, pp. 62, figs. 4*).—In this account of the milk supply of each of the cities mentioned information is given on the magnitude of the business, source of the milk, means of transportation, freight rates, handling the milk in the city, sanitary regulations, and similar topics. Maps are given showing the source of the milk supply of each of the cities.

**On the influence of milk control upon the composition of milk in Gratz,** K. HELLE (*Arch. Hyg., 56 (1906), No. 1-2, pp. 205-207*).—Under the influence of milk control the average fat content of the market milk of this city increased from 2.6 per cent in 1898 to 3.54 per cent in 1905.

**The rapidity of the absorption of odors by milk,** F. BORDAS and TOUPLAIN (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 22, pp. 1204, 1205*).—Milk exposed for several minutes in an atmosphere containing formaldehyde in the proportion of 1:100,000 showed clearly a reaction for this substance. The fresher the milk the more rapid was the absorption.

**Contribution to the study of the bacterial content of milk and of the udder,** R. D'HEIL (*Arch. Hyg. Inst. K. Tierarztl. Hochschule Berlin, 1906, No. 7; abs. in Rev. Gén. Lait, 5 (1906), No. 13, p. 306*).—The author finds bacteria regularly present in the milk cistern and ducts and concludes that they gain entrance through the orifice of the teat. Glandular tissue which contains only a small number of bacteria is believed to possess considerable bactericidal power. The higher bacterial content of machine-drawn milk is considered due to the difficulty of cleansing milking machines.

**The contamination of milk at the dairy,** A. H. STEWART (*Amer. Med., n. ser., 1 (1906), No. 1, pp. 17-21, figs. 9*).—Six experiments are reported which show in a striking manner the value of sterile covered milk pails in lessening the bacterial contamination of milk.

**On the frequency of streptococci in milk,** M. KAISER (*Arch. Hyg., 56 (1906), No. 1-2, pp. 51-89*).—Streptococci were found in 76.6 per cent of 30 samples of milk collected in Gratz and vicinity from November, 1904, to July, 1905. The cultural tests are reported in detail.

**On the streptococci of milk,** P. T. MULLER (*Arch. Hyg., 56 (1906), No. 1-2, pp. 90-107*).—Twenty-one cultures of streptococci isolated from pathological products and 22 from milk samples were studied as regards their power of coagulating milk, hemolytic properties, and behavior toward agglutinating serum.

It was found that nearly all of the milk streptococci curdled milk at the end of 24 hours, while very few of the pathogenic streptococci curdled the samples even at the end of 48 hours. All samples in both series, however, were curdled in 72 hours. The more rapid production of acid by the milk streptococci, however, is not considered as showing any specific difference between the two groups of organisms.

In studying the hemolytic power of the various organisms the cultures were divided into 2 series, the first containing those recently isolated, and the second those grown for some weeks in the laboratory. Of the 13 pathogenic streptococci in the first series 7 showed hemolytic properties, and of 10 in the second series 4 were distinctly and 1 slightly hemolytic. Of 10 milk streptococci in each series, 5 in the first and 3 in the second possessed hemolytic properties. The results, therefore, showed no striking difference between the pathological and milk streptococci as regards hemolysis.

In the agglutination tests 7 out of 11 milk streptococci reacted with an immune serum in a dilution of 1:10, while 2 reacted in a dilution of 1:400. Eight out of 9 streptococci of the pathogenic group gave a positive reaction in a dilution of 1:10 and 4 in a dilution of 1:400. The results are interpreted as showing a close relationship between some of the milk streptococci and pathogenic forms, and this was emphasized by the fact that the milk streptococci which reacted with immune serum in high dilutions were the forms which produced hemolysins.

The author, therefore, concludes from the results of his own and other investigations, which are cited, that there can no longer be any doubt that pathogenic streptococci are present in milk. How frequently these are present is a question yet to be answered.

**The reduction test as a means of determining the freshness of milk, P. T. MÜLLER** (*Arch. Hyg.*, 56 (1906), No. 1-2, pp. 108-204, figs. 5).—In making this test in laboratory work the author uses 4 test tubes, in one of which is put 2 cc. of whole milk and in the others equal quantities of milk diluted with water in the proportion 1:2, 1:4, and 1:8. To each tube is added 0.2 cc. of a 0.2 per cent solution of methylene blue, and the liquid after mixing is covered with a layer of liquid paraffin about 2 cm. in thickness. The samples are then placed in a thermostat at 37° C. and the time required for the reduction of the methylene blue in the whole milk is observed.

This test was applied to numerous samples of market milk showing different degrees of acidity; mixtures of fresh and sour milk; dirty milk; milk to which soda, boric acid, salicylic acid, formaldehyde, and hydrogen peroxid had been added; and heated milk.

For fresh milk obtained in a cleanly manner the time required for the reduction of the methylene blue was 10 or more hours, and for milk delivered by producers directly to consumers during cold weather 6½ to 9 hours. The reduction test of milk obtained from small dealers during the forenoons was 5 to 6 hours during cold weather and 1 to 2¾ hours during warm weather, while that of the samples obtained during the afternoons was ¾ to 3 hours during cold weather and ½ to 1 hour during warm weather. Milk kept at a high temperature showed a shorter reducing period than milk kept at a low temperature.

Curdled milk reduced the methylene blue in a few minutes. The addition of small quantities of sour milk and also of manure to fresh milk shortened greatly the reducing period. The neutralization of milk with soda was without influence on its reducing properties, but the addition of soda to milk poor in bacteria lessened the time required for reduction until sufficient acid was produced to render the milk again neutral or acid.

The addition of preservatives such as boric acid, salicylic acid, and formaldehyde lessened or destroyed the reducing power of the milk. Milk heated for 15 to 30 minutes at 100° C. showed only a small reducing power, which, however, gradually increased the longer it was kept.

The author describes a modified form of the laboratory method which he considers suitable for household use in determining the freshness of milk. When reduction does not occur at the end of 1 hour the milk is considered suitable for infant feeding.

**The testing of market milk, A. LAM** (*Chem. Ztg.*, 30 (1906), No. 39, p. 467).—This is an abstract of a paper presented before the Sixth International Congress of Applied Chemistry.

In testing market milk in regard to its sanitary condition the author determines what he calls the catalase number. Ten cc. of milk is treated with 5 cc. of a 1-per cent solution of hydrogen peroxid and allowed to stand for 24 hours at a temperature of 22 to 35° C. The number of cubic centimeters of oxygen gas liberated is designated the catalase number. For fresh pure milk this varies between 0.3 and 1. In cases of mastitis or tuberculosis of the udder this number is found to be increased. Milk showing a catalase number of over 3 is considered unfit for use.

The author has also found polarization of the milk serum of value for this purpose. While the normal index of refraction lies between 5 and 5.5, it was found to be 1.2, 1, and 0.73 in the case of diseased animals. The freezing point, however, remained constant.

**The care of composite milk samples**, I. C. WELD (*New Hampshire Sta. Bul.* 126, pp. 181-184, figs. 5).—Brief notes are given on the taking of composite milk samples and on preserving them with formalin, potassium bichromate, or corrosive sublimate.

**On the combination of lactic acid with casein in lactic fermentation**, C. RICHER (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 14, pp. 650, 651).—When milk was allowed to coagulate spontaneously the curd was found to fix about 5 times the amount of lactic acid contained in the same volume of whey.

**A test of tin can separators**, C. H. ECKLES (*Missouri Sta. Bul.* 68, pp. 23-34, figs. 4).—Tests were made of 3 forms of so-called separators which consist of 2 cans one within the other. The milk is placed in the inner can and cold water in the outer can surrounding the milk.

The average results of 42 trials with these cans showed that the skim milk contained 1.39 per cent of fat, equivalent to a loss of 22.56 per cent of the fat. The 3 patented cans were compared with shallow pans, a dilution can, the centrifugal separator, and a homemade can. Under the conditions of the comparison the shallow pans gave better results than either the dilution or double cans. The homemade can costing \$1.50 gave equally good results as the patented cans costing from \$6 to \$10.

**Creamery problems**, C. L. BEACH (*Connecticut Storrs Sta. Bul.* 40, pp. 38-47).—Of 1,362 patrons of 18 creameries in 1903, 256, or 19 per cent, were using centrifugal separators, while the remainder were using the Cooley system of cream raising. Comparative tests were made of these 2 methods.

The average of 13 samples of skim milk by the Cooley system showed the presence of 0.27 per cent of fat, and the average of 36 samples of separator skim milk showed the presence of 0.056 per cent. It is estimated that with a herd of 10 cows the hand separator effects a saving of \$25.48. Five types of centrifugal separators were compared, the fat content of the skim milk ranging from 0.038 to 0.076, which difference for a herd of 28 cows is estimated as equivalent to \$7.95 for one year.

The fat content of 10 samples of skim milk was determined by gravimetric analysis and by the Babcock test, using 17.6 cc. and 25 cc. of acid. The average results for the 3 methods were, respectively, 0.144, 0.046, and 0.063 per cent. Even with the excess of acid the Babcock readings were much lower than the gravimetric determinations.

Readings of Babcock tests were made at temperatures of 130 and 180° F., the average difference on 10 samples being 0.42 per cent. This emphasizes the importance of making the readings at a uniform temperature.

Variations in the weight of 18 cc. of cream containing different percentages of fat are given in tabular form to show the importance of weighing samples.

In 14 experiments a starter made from a pure culture was compared with a skim milk starter. The average score of the butter from the 14 churnings when the pure culture starters were used was 94 and of the butter from the churnings ripened with skim milk starters 94.1. A table shows the bacterial content of 12 samples of butter, of the cream from which the butter was made, and of the starter used in ripening the cream.

**Creamery cold storage**, J. A. RUDDICK (*Canada Dept. Agr., Dairy Comr. Branch Bul.* 10, pp. 14, pls. 2).—This furnishes information on the subject of creamery cold storage and embodies the results of recent experiments conducted for the purpose of testing various materials used for the purpose of insulation. Specifications are given

for the construction of creamery refrigerators on both the air circulation and cylinder systems.

**The manufacture of whey butter at Swiss cheese factories,** E. H. FARRINGTON (*Wisconsin Sta. Bul. 132, pp. 32, figs. 17*).—This bulletin, which is published in both English and German, contains descriptions of the methods employed in making whey butter in Swiss cheese factories in Wisconsin, with suggestions for the improvement of these methods.

The cold process of skimming the whey is considered not only wasteful but unsatisfactory on account of the extremely sour condition in which the whey is returned to the farmers, and also because the cream so obtained is not suitable for the manufacture of good butter. It is believed that this method should be abandoned. The hot process is considered much superior to cold skimming in that much more fat is recovered and the cream is in a sweet condition, making it possible to produce butter of good flavor.

About 2 years ago some experiments were made at the University of Wisconsin dairy school in skimming whey with a centrifugal power separator, and since then this method has been tried on a practical scale in a number of factories. According to the author's observations centrifugal separation is much superior to the other methods. The separator removes nearly all of the fat and permits the making of butter equal in quality and water content to creamery butter. The objections made to installing separators in cheese factories are their cost and the expense for power. Results have shown, however, that with improved methods of skimming and churning the surplus whey butter may more than pay for the additional cost.

In addition to the separator there is needed in the Swiss cheese factories, according to the author, a cream vat of some sort in which the whey cream may be ripened and cooled before churning and improved methods of working the butter.

The suggestions made for improving whey butter cover skimming the whey, ripening the cream, making and using a starter, churning the cream, working the butter, and other topics.

**Some facts about moisture and its effects on butter,** G. L. MCKAY (*Hoard's Dairyman, 37 (1906), No. 16, pp. 432, 433*).—In discussing this subject the author gives data obtained at the Iowa station and observations made abroad.

It is not believed that the poor keeping quality of butter is due to an excess of moisture so much as to unsanitary methods pursued and the use of overripe cream. The author considers that "there is no danger of any maker incorporating too much water who churns his butter in a granular condition and does not resort to abnormal methods, such as churning at high temperatures, washing with warm water, overchurning, or working the butter in water."

**On the composition of Dutch butter made in the creameries placed under State control,** T. VAN SILLEVOLDT (*Gen. Dir. Agr. Min. Agr., Indus. and Trade [Netherlands], [Circ.], 1905, No. 5, pp. 31; 1906, Jan., Feb., Mar., Apr., pp. 4 each*).—Of 4,340 samples of butter analyzed during October, November, and December, 1905, 78 showed a lower Reichert-Meissl number than 24. The analytical results are hereafter to be published monthly, with a special report every 6 months on the samples showing low Reichert-Meissl numbers.

**Bacteriological examinations of the butter of Stuttgart,** A. REITZ (*Arch. Hyg., 57 (1906), No. 1, pp. 1-28, figs. 5*).—This is a detailed report of the inoculation experiments with guinea pigs made to determine the presence of tubercle bacilli in butter, previously noted from another source (E. S. R., 17, p. 1109). Tubercle bacilli were present in 8.5 per cent of the samples.

**Fungi in cheese ripening: Camembert and Roquefort,** C. THOM (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 82, pp. 32, figs. 3*).—This reports in detail the mycological studies referred to in the previous bulletin (E. S. R., 17, p. 79) on the manufacture of Camembert cheese in the United States.

In the manufacture of soft cheese of the Camembert type the curd is rendered acid by the action of lactic-acid bacteria, and later alkaline by the growth of various species of fungi which, through the production of enzymes, break down the curd to a greater or less extent.

"The Camembert *Penicillium* (*P. camemberti*) is the only species so far studied with which the particular appearance and texture sought in the ripened Camembert can be produced from curd soured by lactic bacteria without producing any objectionable flavor.

"*Oidium lactis* is always found upon Camembert cheese and so closely associated with the presence of the flavor as to indicate its agency in flavor production, though only circumstantial proof of such function has been possible thus far. The participation of bacteria in flavor production is not excluded by these results.

"Other species of fungi have been shown to produce variations in this flavor such as have been often found in certain market cheeses."

The Roquefort *Penicillium* (*P. roqueforti*) is the only fungus found necessary to produce the typical flavor of Roquefort cheese. This mold has also been found in imported Stilton, Gorgonzola, and Brinse cheese as well as in the Roquefort.

*Oidium lactis* is the only fungus which has been found regularly upon Limburger, American Brie, Isigny, and related types of cheese.

Technical descriptions are given of the 2 forms of *Penicillium* under the new names *P. camemberti* and *P. roqueforti* and of *Oidium lactis*.

**A new method of making dry red wine**, F. T. BIOLETTI (*California Sta. Bul.* 177, pp. 36, figs. 14).—Wine-making experiments during the year have abundantly verified, according to the author, the claims made for the method given in Bulletin 167 of the station (E. S. R., 17, p. 183).

"The most important conclusion to be drawn from these experiments is that sound dry wine of fair quality can be produced in the upper San Joaquin Valley and similar regions from the varieties of grapes growing there, simply by ordinary attention to cleanliness, the sterilization of cooperage, and more than ordinary attention to the control of temperature.

"For white wines a thorough preliminary defecation of the must by means of sulphur fumes and the use of pure yeast or yeast starters is advisable.

"For red wines some form of cooling machine is essential, and the temperature of the fermenting wine should never exceed 95° F., and if possible should be kept below 92° F. This can be easily and perfectly done by means of the cooling machine described in Bulletin No. 174 (E. S. R., 17, p. 1110).

"The grapes both for white and red wines should be thoroughly ripe. Ripeness must be determined by the flavor and appearance of the grapes more than by the amount of sugar they contain. We can not hope to get the best results from imperfectly ripe grapes even if they contain 22 per cent of sugar. Some varieties in the climate of the San Joaquin Valley are not perfectly mature for wine-making purposes until they contain 25 per cent of sugar or more. Better results are to be obtained by diluting and, if necessary, adding tartaric or citric acid to over-ripe grapes in this region than by attempting to make wine from under-ripe grapes which have not developed the color, body, and flavor necessary for the production of good wine."

The cost of applying this method on a large scale is yet to be ascertained, and with this in view a plan is given of a cellar suitable for working 50 tons of red grapes per day along with an outline of the method of operation.

**The artificial ripening of grapes**, L. MATHIEU (*Rev. Vit.*, 25 (1906), No. 640, pp. 313-316).—The results are given of an experiment in which wine was made from grapes partially dried in an evaporator. The work shows that it is possible to partially evaporate grapes in order to concentrate the must without any injurious effects or cooked taste to the wine. The process favors the production of a wine of superior quality.

## VETERINARY MEDICINE.

**Proceedings of the American Veterinary Medical Association** (*Proc. Amer. Vet. Med. Assoc.*, 42 (1905), pp. 506, pls. 20).—This volume contains an account of the meeting of the forty-second annual convention of the American Veterinary Medical Association, held in Cleveland, Ohio, August 15–18, 1905.

As usual, in the proceedings lists are given of the officers, committees, resident secretaries, and honorary and active members of the society. The address of welcome was given by the mayor of Cleveland, T. L. Johnson, and was responded to by R. R. Bell. The president's address, by M. E. Knowles, contained references to various veterinary matters, particularly to the cooperation of veterinarians and physicians and the importance of the veterinarian in the promotion of general sanitation.

In the reports of resident State secretaries attention is called to the condition of health in domesticated animals in the various States and Territories. In Arizona and New Mexico, particular attention was given during the year to sheep scab; in Colorado to cattle mange, loco weed, and bovine tuberculosis; in Connecticut, Cuba, and Porto Rico, to the legislative control of animal diseases; in Maine, to tuberculosis and glanders; in Maryland, to anthrax and forage poisoning; in Michigan, to rabies; in Minnesota, to hemorrhagic septicemia and swamp fever; in Mississippi, to anthrax and Texas fever; in Nebraska, to various parasitic diseases; in Ohio, to tuberculosis and swine plague; in Ontario, to actinobacillosis and hog cholera; in Pennsylvania, to legislation regarding experimental veterinary work; in the Philippines, to surra, rinderpest, and foot-and-mouth disease; in Tennessee, to glanders and influenza; in Texas, to Texas fever and cattle mange; in Vermont, to anthrax and glanders; and in Wisconsin, to the present status of the veterinary practitioner.

The Report of the Committee on Intelligence and Education, by C. J. Marshall et al., contains a general review of matters of interest to veterinarians, a digest of recent veterinary literature, and a detailed account of the quality of instruction and the curricula in various veterinary schools in this country.

In the report of the Committee on Diseases, by C. H. Higgins et al., attention is devoted to methods of keeping the clinical history of cases, the need of more veterinary research work, and the discussion of rabies, *Bacillus necrophorus*, roup in chickens, and the State control of tuberculosis. The present status of the movement for securing legislation regarding army veterinarians was presented by a committee consisting of W. H. Lowe et al.

An unusual number of papers were read at the various meetings of the convention and are printed in the proceedings. It is impossible to refer to these except in the briefest manner. The Artificial Immunization of Cattle Against Tuberculosis was discussed by L. Pearson and S. H. Gilliland. The authors report considerable success in the use of various vaccinating methods and believe that these methods promise to become much more effective. Papers were also presented on The Pathology of Tuberculosis, by C. Schulin, and by R. H. Harrison on Unusual Lesions of Tuberculosis Found in Abattoir Inspection. The method of controlling glanders adopted by a French firm which employs a large number of horses was discussed in a paper by E. Lavalard. The method consists in the general use of mallein, furnishing as favorable conditions as possible for suspected horses in quarantine, and the exercise of great care in introducing strange horses into a healthy herd.

The Spavin Group of Lamenesses was discussed by W. L. Williams et al. This account is one of the most important thus far published on the general subject of spavin and enters, in great detail, into the pathology, peculiar forms, etiology, and treatment of the disease by different methods.

Mention should also be made of the following papers: The Clinical Examination of the Blood of the Dog, by S. H. Burnett and J. Traum; Cultivation of *Trypanosoma equiperdum*, by J. R. Mohler; Twenty-seven Years' Experience in Veterinary Practice, by J. V. Newton; Accidents and Sequelæ of Surgical Operations, by L. A. Merillat; Indications for Neurectomies of the Pelvic Limb of the Horse, by R. C. Moore; The Profession and the Advancement of Science, by D. A. Hughes; Stable Ventilation, by M. H. Reynolds; The Status of Therapeutics, by P. A. Fish; A Review and Criticism of the Eighth Decennial Revision of the Pharmacopœia of the United States, by E. L. Quitinan; Hydrothorax in the Horse, by G. B. Jones; and A New Treatment for Gastro-Intestinal Catarrh of Milk-Fed Calves, by L. A. Klein.

**Annual report of the State board of live stock commissioners of Ohio,** P. FISCHER (*Ann. Rpt. Bd. Live Stock Commr. Ohio*, 4 (1905), pp. 71, figs. 14).—The diseases which have occurred in Ohio to an extent which attracted the attention of the live stock board during the past 4 years included the most important diseases of horses, cattle, sheep, hogs, cats, and fowls.

The work of the board of the live stock commissioners has extended in many directions, until at present it is considered that the services of additional veterinarians are needed. As usual in these reports maps are given showing the location of anthrax, actinomycosis, foot-rot, glanders, hog cholera, swine plague, keratitis, nodular disease, rabies, mange in horses, tuberculosis, and Texas fever. In the case of each one of these diseases a brief account is presented of the work of the State veterinarian and his assistants in controlling the outbreaks.

In an appendix to the report copies are given of laws relating to live stock and the duties of the board of live stock commissioners of Ohio.

**Abstracts of work done in the laboratory of veterinary physiology and pharmacology. III,** P. A. FISH ET AL. (*Ithaca: N. Y. State Vet. Col., 1906, pp. 44*).—An account is presented of a case of urethral calculus in the dog (pp. 3-8), arecolin hydrobromate and its action upon dogs and cats (pp. 9-13), the effects of sulphurous acid upon peptic and tryptic digestion (pp. 14-21), ergot as an abortifacient (pp. 22-29), the status of therapeutics (pp. 30-34), the structure and function of the digestive tract of the chicken (pp. 35-42), and the effect of sulphurous acid upon the urinary constituents (pp. 43, 44).

In experiments with ergot in which cats were used, it was found that doses of this drug would produce abortion within 24 hours. In some cases the young were killed, while in others they seemed not to be affected. It is concluded, therefore, that ergot exercises an abortifacient action of considerable power. Attention is called to the present status of therapeutics as a profitable subject of study for veterinarians. New drugs are constantly being put on the market, and from the great number thus offered for use the veterinarian must select, as a result of experiment, those which really give promise of good results. Some of the new remedies are superior to the old ones used for specific purposes, while others are no better or quite inferior.

**The Bang method of controlling tuberculosis with an illustration of its application,** H. A. HARDING, G. A. SMITH, and V. A. MOORE (*New York State Sta. Bul.* 277, pp. 81-109).—A general account is presented of the nature of tuberculosis, together with a description of the Bang method of controlling the disease and the use of tuberculin.

In December, 1900, one animal in the station herd was found to be tuberculous and on this account the tuberculin test was given to the whole herd. As a result of the test a reaction was obtained with 8 cows and 7 young cattle in a total of 28. These animals were kept under observation, and in 1901 the Bang system was put in operation for the purpose of determining its value under the conditions which prevailed in the station herd.

The method was applied to a total of 30 animals, 13 of which were healthy and 17 tuberculous. During the 4 years of the test this herd produced 23 heifer calves,

one-half of them coming from the tuberculous animals. The calves obtained from the tuberculous cows were not allowed to suck their mothers nor to drink tuberculous milk until after it had been pasteurized at a temperature of 185° F. The record of the tuberculous part of the herd is given in a tabular form and notes are also presented on autopsies on diseased animals and an examination of the meat of tuberculous animals killed for beef.

**A healthy herd from a tuberculous herd**, F. H. HALL, H. A. HARDING, G. A. SMITH, and V. A. MOORE (*New York State Sta. Bul.* 277, popular ed., pp. 8, fig. 1).—A popular summary of Bulletin 277, noted on page 1189.

**Combating tuberculosis in farm animals**, A. VAN LEEUWEN (*Tijdschr. Veeartsenijk.*, 33 (1906), No. 6, pp. 340-345).—This is a controversial article in which the author takes the position that a governmental requirement of notification of all cases of tuberculosis in domesticated animals would work great hardship. It is frequently impossible for the owner to determine when an animal is affected with the disease, in fact the most experienced veterinarians sometimes have to make use of all means of diagnosis in order to determine the matter.

**Distribution of tuberculosis in suspected and nonsuspected herds in Wisconsin**, H. L. RUSSELL and E. G. HASTINGS (*Wisconsin Sta. Bul.* 133, pp. 15, figs. 3).—On account of the insidious nature of tuberculosis and also on account of the fact that the disease has been found very prevalent in certain dairy herds the present bulletin has been prepared for the purpose of furnishing a concise description of the tuberculin test and further data regarding the results obtained from this test and its reliability.

Brief summaries are presented of some of the previous work done by this station on tuberculosis, and recommendations are made regarding the disinfection of stables. For this purpose the authors recommend a whitewash made of fresh unslaked lime, and also saturated solution of copperas.

**Are tubercle bacilli coughed up by cattle affected with pulmonary tuberculosis?** J. A. KLAUNERS (*Tijdschr. Veeartsenijk.*, 33 (1906), No. 6, pp. 351-353).—From statistics regarding the organs affected in cases of bovine tuberculosis it appears that the lungs were diseased in 40,306 cases among a total of 46,092. On the basis of these facts and the further fact of the frequent infection of the lymphatic glands of the throat and pharynx, the author justifies the conclusion that tuberculosis in cattle is very frequently contracted by inhalation and that, therefore, the tubercle bacilli which cause such infection probably come from other cows affected with the pulmonary form of the disease.

**Serum vaccination against anthrax**, G. GAZZANIGA (*Clin. Vet. [Milan]*, 29 (1906), No. 8, pp. 203-205).—Brief notes are given on vaccination for the purpose of preventing anthrax by the method which requires the use of two vaccines. This method has given satisfactory results in the author's hands.

**Blackleg**, W. H. DALRYMPLE (*Louisiana Sta. Bul.* 85, pp. 7, fig. 1).—Inquiries are frequently received at the station regarding the nature of blackleg and suitable treatment for this disease. It is suggested that probably many young scrub cattle of little value die of blackleg from year to year without any investigation of the cause of the disease. This fact may account for the persistence of the disease in certain localities. Notes are given on the cause, symptoms, treatment, and preventive vaccination for blackleg.

**Vaccination against blackleg**, K. R. KUIPERS (*Tijdschr. Veeartsenijk.*, 33 (1906), No. 6, pp. 345-351).—Various methods were tried in vaccinating calves against blackleg. The author used vaccine thread, dried vaccine, and material in solution. The best results were obtained from the last-named method. Brief notes are given on the pathological anatomy of blackleg based on a number of autopsies.

**Texas fever with methods for its prevention**, J. R. MOHLER (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 78, pp. 48, pl. 1, figs. 3).—The author presents a valuable

summary of information relating to the nature of Texas fever and the practical means of its eradication.

The subject-matter includes a definition of the disease; notes on its history and distribution; etiology; life history of the cattle tick and its agency in distributing Texas fever; means of distinguishing between this tick and other species of ticks; the loss caused by ticks aside from their agency in carrying Texas fever; symptoms, course, and termination of Texas fever; and treatment and prevention of the disease. Definite and practicable plans are presented for the arrangement of farms so that cattle may be freed from ticks and the ticks ultimately eradicated by the system of feed lots and pasture rotation. The method of immunization by means of the blood of recovered cattle is also described.

**Vaccination against foot-and-mouth disease**, N. L. BUONSANTI (*Clin. Vet. [Milan]*, 29 (1906), No. 6, pp. 145-148).—Numerous experiments have been carried out in vaccinating cattle against foot-and-mouth disease by means of a mixture of 0.03 cc. of virulent lymph and 0.5 cc. of bovine serum. For vaccinating hogs and sheep the author has used a concentrated serum from a horse previously inoculated with the virus. The results thus far obtained are promising.

**The treatment of epizootic abortion**, E. THIERRY (*Jour. Agr. Prat., n. ser.*, 11 (1906), No. 7, pp. 208, 209).—A number of investigators have found that good results may be obtained from the use of antiseptic solutions, such as the use of corrosive sublimate, 1:1,000 parts in water, and a solution of iodine and iodide of potash. An internal prophylactic treatment, with doses of 5 to 6 drams of iodide of potash, has also given satisfactory results.

**The poisoning of cattle by tobacco decoction**, F. PEUCH (*Jour. M'd. Vét. et Zootech.*, 57 (1906), Feb., pp. 78, 79).—Two heifers which had become greatly infested with fleas were treated by the owner with tobacco decoction as obtained from the manufacturer and diluted with an equal amount of water. Within a few hours serious symptoms of poisoning occurred, the animals being unable to rise and in a state of extreme coma. Considerable irritation of the skin was also produced. Recovery took place on the following day.

Attention is called by the author to the fact that tobacco decoction, diluted with 10 parts of water, is effective in such cases and ordinarily does not produce poisonous effects.

**Vaccination for hog cholera**, L. BRUSASCO (*Gior. R. Soc. ed Accad. Vet. Ital.*, 55 (1906), No. 6, pp. 123-125).—References are made to some of the more important publications on this subject and a table is given showing the results of vaccination against hog cholera during 1905. From this table it appears that the percentage of mortality in nonvaccinated hogs was 79.6, while in vaccinated animals it was 17.4.

**Combating swine plague**, FORTH (*Berlin. Tierarztl. Wchnschr.*, 1906, No. 7, pp. 175-128).—From the standpoint of the veterinary police, swine plague includes hog cholera as well as swine plague proper.

Although these diseases frequently occur simultaneously in the same animal, the official veterinary police must depend largely upon the clinical symptoms and the infectiousness of the disease in reaching a diagnosis. The persistent spread of swine plague is attributed to its already wide distribution, the chronic course of many cases, the aversion to strict quarantine, traffic in live pigs, too early period of weaning pigs, neglect of hygienic precautions, and the extensive use of improved breeds, some of which are less resistant than grade hogs.

**Antidotes for poisoning by *Gastrolobium calycinum***, E. A. MANN (*Jour. Dept. Agr. West. Aust.*, 18 (1906), No. 1, pp. 50, 51).—Feeding experiments were carried out with this plant in the case of sheep in order to test various antidotes for the alkaloid poison in the plant. Permanganate of potash in acidulated water appeared to have no influence in checking the poisonous effects. Negative results were also

obtained with sodium bicarbonate. The action of tannic acid, however, when given as a drench in doses of  $\frac{1}{2}$  oz. appeared to be quite satisfactory.

**Suggestions as to dipping sheep** (*Jour. Bd. Agr. [London]*, 12 (1906), No. 11, pp. 678-681).—Directions are given for cleaning dipping tanks and catching pens, mixing dips, trimming the wool, and related matters, together with notes on the proper time of dipping and on the repetition of the process.

**Infectious broncho-pneumonia of lambs**, E. THIERRY (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 4, pp. 110-112).—Opportunity was had for studying a rather serious outbreak of pleuro-pneumonia of lambs. As a result of this study it appears that the disease is of bacterial origin, although the micro-organism was not isolated. In controlling the disease the usual procedure in cases of infections is recommended, viz, isolation of diseased animals and thorough disinfection.

**Further notes on the pathogenic organism of pneumonia and its biology**, LORENZ (*Berlin. Tierarztl. Wchnschr.*, 1906, No. 9, pp. 145-147, figs. 3).—As reported in previous articles by the author, an organism was found in the skin of horses affected with pneumonia several days after recovery.

This organism was obtained under the observation of the strictest rules of asepsis and proved to be a streptococcus when cultivated on artificial nutrient media. The streptococcus appears to develop from minute rods. This organism when used in inoculation reproduces the disease. The author believes as a result of a further study of this organism that it is really a plasmodium or sporozoan, which may be observed in various forms, such as spores and rods, which may unite to form streptococcus.

**The demonstration of the organism of pneumonia in horses and its biology**, LORENZ (*Berlin. Tierarztl. Wchnschr.*, 1906, No. 7, pp. 113-115, figs. 8).—On account of the irregular manner in which an outbreak of pneumonia usually progresses in a herd of horses it has been assumed by many investigators that the organism of this disease must require an intermediate host, and in this connection flies have been suggested.

The author finds, however, that the organism persists for a long time in the subcutaneous tissue. It has been found in considerable numbers in such locations and kept in pure cultures. When the virus thus obtained was inoculated into rabbits, cocci were found in the blood 20 hours after inoculation. Since the organism described by the author appears to be the true cause of pneumonia, it is believed that a method of vaccination can now be readily devised which will protect animals against the disease.

**Pleuro-pneumonia**, MOUQUET (*Bul. Soc. Cent. Méd. Vét.*, 83 (1906), No. 4, pp. 114-117).—Notes are given on the symptoms of pleuro-pneumonia in horses in which septic edema occurred and an ammoniacal fermentation in the thoracic cavity. A study was made of the reaction and chemical properties of the serous fluid in the pleural cavity and the gases developed by the ammoniacal fermentation in this fluid were studied.

**Experiments with contagious coryza, with especial reference to the immunization of rabbits against this disease**, J. LUDWIG (*Monatsh. Prakt. Tierheilk.*, 17 (1906), No. 7-8, pp. 289-321).—The literature on this disease is critically reviewed in connection with a short bibliography.

It appears from experimental work carried out by the author that rabbits may be actively immunized against contagious coryza. A number of methods are successful in accomplishing this result, but the best seems to be found in the use of cultures killed by means of heat or by the use of iodine trichlorid. The active immunization may be brought about rapidly and may be carried to a high degree by repeated inoculations. The organism of contagious coryza is practically nonvirulent for rabbits when inoculated hypodermically, but in intraperitoneal injections it rapidly produces death. From the blood of rabbits thus immunized a serum may be obtained which will protect other animals from infection.

**Experiments in protective inoculation against contagious coryza with dead streptococci,** T. KIRT (*Monatsh. Prakt. Tierheilk.*, 17 (1906), No. 7-8, pp. 363-367).—The experiments reported in this paper were carried out on colts. It was found possible to immunize colts to a considerable extent by inoculating them with dead cultures of the streptococcus of contagious coryza. The method, however, has little to recommend it in actual practice, since in order to obtain a protective immunity 6 or 7 treatments must be given. Passive immunity which may be produced by means of injections of serum has only a short duration.

**Kimberley disease in horses,** R. E. WEIR ET AL. (*Jour. Dept. Agr. West. Aust.*, 12 (1905), No. 1, pp. 60-63).—This disease has a course of variable duration and is characterized by symptoms of congestion and derangement of the brain.

It appears that the extraordinary mortality which occurs from attacks of this disease can not be attributed solely to one cause. The presence of parasites, however, particularly *Spiroptera megastoma*, may be looked upon as a predisposing cause, in connection with coarse forage and the ingestion of large quantities of green food. In treating the disease the author recommends antipyrin 3 times daily in doses of 1 dram together with a mixture containing  $\frac{1}{2}$  dram calomel and  $\frac{1}{2}$  oz. ginger.

**A skin disease in horses affecting only the white markings,** E. F. MARTIN (*Vet. Rec.*, 18 (1906), No. 922, pp. 628, 629).—In Calcutta the author observed a number of cases of skin disease in Australian horses which had just been landed. The white parts only were affected and appeared as if blistered. The disease was attributed to an attack of insects, but the exact species was not known.

**Osteomalacia in Tonquin,** J. SOURREL (*Rev. Gén. Méd. Vét.*, 7 (1906), No. 77, pp. 233-248, figs. 3).—During the years 1901-1904 the author had occasion to study osteomalacia in horses and mules in Tonquin.

It was found that the disease appears after a varying period following upon exposure or introduction to an affected region. The usual period ranges from 6 months to 2 years. Animals first appear lame and depressed, later malformations may appear particularly in the form of enlargements of the flat bones and short articular bones. Fractures of the long bones in the leg may occur at any time during the course of the disease. Ultimately the stage of extreme cachexia results, so that prognosis is always serious.

It was found that osteomalacia occurs in regions where there is plenty of lime in the soil and in the forage plants as shown by analysis. The absence of lime could, therefore, not have been the cause in the cases observed by the author. It is believed that the disease is of infectious origin, but the organism has not been isolated. Therapeutic treatment is not very successful, but some benefit was derived from the use of pilocarpin, purgatives, strychnin, and feeding green forage plants, for which purpose the author recommends the use of *Panicum equinum*.

**Use of artificial impregnator in horse breeding,** L. L. LEWIS and W. L. ENGLISH (*Oklahoma Sta. Circ.* 5, pp. 8, figs. 6).—The importance and general use of the artificial impregnator by stockmen led the station to send out a circular letter of inquiry regarding the methods in common practice.

It appears that there are two forms of impregnator in general use, the straight and the curved. The latter is preferred, and may be used with or without a vaginal speculum. If a breeding bag is used on the stallion a speculum will be found unnecessary. Before service it may be well to close the neck of the uterus with a rubber plug. After service the plug is removed at once, a part of the semen injected into the uterus and the rest used to impregnate other mares. Before transferring the semen the syringe should be warmed in water at a temperature of 100° F. and the transfer should take place without delay.

Experiments in preserving semen in vials for a period of 3 hours or more showed that a temperature of 100-103° F. is less favorable to the vitality of the spermatozoa than 85° F. In Oklahoma the breeding bag is used by about two-thirds of those who

impregnate mares artificially. As was to be expected, better success attends the efforts of the breeder the longer he practices the method.

**The effect of experimental epilepsy on poisoning by tetanus toxin, L. CESARI** (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 8, pp. 397-399).—It has been claimed by a few investigators that the effects of tetanus toxin may be somewhat overcome by passing an alternating electro-current through affected animals.

This was tested on guinea pigs by the author with the result that little benefit was found from the practice. Guinea pigs inoculated with tetanus toxin showed the epileptiform crisis of the disease during the passage of an alternating current in the same manner as shown by normal animals. The muscular contractions disappeared for a few minutes after the epileptiform crisis but soon recurred again. Animals treated in this manner lived little longer than the control animals.

**Treatment of demodectic mange, CEDÉAC** (*Jour. M'éd. V'et. et Zootech.*, 57 (1906), Feb., pp. 80-83).—Attention is called to the undesirability of attempting to treat all forms of mange and parasitic skin diseases by similar lines of treatment. In some forms of mange caused by demodectes as well as phlegmonous dermatitis it is usually best to scarify the affected parts and apply tincture of iodine.

**The bacillus of mouse typhoid and related forms, R. TROMMSDORF** (*Arch. Hyg.*, 55 (1906), No. 3, pp. 279-298).—An attempt was made to determine the relationship and independence or identity of various bacteria related to the mouse typhoid bacillus.

In experiments along this line a series of agglutination tests were made, but it was found that agglutination is a very uncertain method of determining the identity or specific individuality of bacteria of this group. Apparently *Bacillus enteritidis* is distinct from the other bacteria of this group, while there are various groups under the paratyphoid bacillus as well as of the hog cholera bacillus. It was impossible by means of agglutination tests to differentiate between the mouse typhoid bacillus, hog cholera, paratyphoid, and meat-poisoning bacillus.

Attention is called to the fact that the bacilli which have been used for the destruction of mice as well as the hog cholera bacillus may be pathogenic for man. The author believes, however, that there is no justification for prohibiting the use of cultures of mouse typhoid bacillus in the destruction of field mice.

## RURAL ENGINEERING.

**Irrigation from Snake River, Idaho, H. G. RASCHBACHER** (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 65, pp. 16).—The territory covered by this circular extends from the Wyoming line to Salmon River, a distance of about 200 miles. In this area there is about 800,000 acres at present under ditch, and the proposed works will cover about 200,000 acres additional. Probably not more than half of this land is at present under cultivation, leaving a large area which is awaiting settlement.

This circular is devoted to the conditions which a new settler will meet in making a home in this section. With few unimportant exceptions, the settlers must secure rights from companies building ditches, there being little if any opportunity for securing rights directly from the streams. Most of the canals are built either under the Carey Act, under which the lands and water rights are disposed of on terms specified in contracts with the State, or under the reclamation act, which provides for the payment by the settler of the actual cost of the construction of the works, the lands being taken up under the homestead law, which requires the payment of land office fees only.

The prices of water rights under these various projects vary from \$15 to \$25 per acre. The expense which must be met by the new settler during the first year is estimated as follows, the full price of the water right being included in this estimate.

This, however, need not be paid during the first year, but may be distributed over a series of years.

First cost of the land and water right.....	\$25.50
Fencing material.....	3.00
Labor:	
Grubbing sagebrush.....	3.50
Plowing.....	2.50
Seeding.....	.50
Leveling and marking.....	1.00
Ditching.....	2.00
Irrigating.....	2.00
Total cost per acre.....	40.00

The circular contains also the record of a number of crop experiments made at Twin Falls during the season of 1905.

**Results of experiments on irrigated meadows,** TACKE (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 9, pp. 96-101).—The experiments described were started in 1900 on meadow lands belonging to the agricultural improvement association of Bruchhausen-Syke-Thedinghausen.

Three types of soil were selected, a clayey loam meadow with a layer 25 to 30 cm. deep, rich in humus, a low moor, and a light sandy heath. These tracts were subdivided and given varying quantities of Thomas phosphate meal and kainit, with and without irrigation. The plats were irrigated by running and still water so as to compare the methods.

The average yield per acre without fertilizers on the first tract was increased 77 per cent by irrigating with running water, and 50 per cent by flooding in checks. With the application of a small amount of Thomas phosphate (150 kg. per hectare annually) there was a further increase of about 33 per cent, while additional quantities showed very small increases in the crop. Kainit alone showed no increase at all when applied at the rate of about 500 kg. per hectare annually, as the lands were not deficient in potassium salts. The other tracts show quite similar results.

In all cases the method of irrigating with moving water appears to give larger yields than the check-flooding method, averaging on the first tract 28 per cent greater, on the second 34 per cent, while on the third the advantage is even more marked. The running water is applied by ridging the land, and apparently not by furrows as in the United States. The author urges independent local experiments and cautions against accepting the data given as applicable under different conditions of soil and ground water.

**Irrigated lands in Idaho** (*The State of Idaho. Boise, 1905, pp. 59-62*).—A summary of irrigation statistics is presented, showing 3,600 miles of canals costing nearly \$10,000,000 and covering over 2,000,000 acres, of which 840,000 are now under cultivation. The publication contains also articles on projects under the Carey Act and the Reclamation Act, and brief descriptions of irrigation systems by counties. The report is profusely illustrated.

**[Irrigation in Wyoming]** (*The State of Wyoming. 1905, pp. 54-79, pls. 6*).—Under the titles Public Lands and Irrigation Projects, State Lands, and How to Obtain a Right to Use Water in Wyoming, a review is given of Reclamation and Carey Act projects, ditches built and projected by private parties, and the laws relating to public lands and water rights.

**Method and cost of constructing cement pipe in place,** H. P. GILLETTE (*Engin. Rec.*, 53 (1906), No. 10, pp. 349, 350, figs. 2).—The Ransome method of making continuous cement sewer pipe in place, which is described here, suggests the use of the same machine for drain pipes.

The device consists of a core 10 ft. long, with a sectional sheet-iron mold. The cement is rammed into place by hand, and the whole machine is moved gradually forward by winding up a cable by a lever and ratchet windlass. The actual cost of laying 8-in. pipe at Rochester, N. Y., was 6.6 cts. per foot, and for 12-in. pipe 10.25 cts. per foot, 300 to 400 ft. a day being laid with a crew of 7 or 8 men. While the pipes laid are said to be as tight as cement-jointed vitrified pipe, it would not be difficult to make them porous enough for drainage by using less cement or by providing openings.

**An investigation of the ancient hydraulic works in Algeria,** S. GRELL (*Paris: Govt., 1902, pp. 143, figs. 27*).—This report consists of descriptions of hydraulic works of Roman origin found in the various provinces of Algeria, written by local administrative officers, engineers, or army officers familiar with particular localities. There are described about 80 barrages, 30 reservoirs, 20 aqueducts, and a large number of smaller hydraulic works formerly used for irrigation or city water supplies.

**Strainers for driven wells,** D. H. MAURY (*Engin. News, 55 (1906), No. 10, pp. 260, 261, figs. 3*).—While fine strainers have been generally favored because they exclude fine sand, their capacity and durability are low.

The principle of the coarse strainer is that fine sand is freely admitted and may be pumped out, thus washing all the fine material from a zone surrounding the strainer and creating what is virtually a strainer of clean gravel having a large capacity, and since a certain initial velocity is required to start fine material toward the well, no silt will be drawn in when pumping any less water than the maximum capacity of the sand pump.

The author describes several well-strainers and the methods of perforating well casings after driving.

**Mountain road construction in Idaho,** E. B. DARLINGTON (*Engin. News, 55 (1906), No. 11, pp. 282, 283*).—The legislature of Idaho in 1905 authorized the expenditure of \$50,000 for mountain roads, under the supervision of a State commission, the cost of new roads to be divided with the community benefited.

Over 100 miles of road have already been built or are nearing completion under this law. It is the policy of the commission to spend only \$500 to \$1,000 per mile, the roads being 8 to 12 feet wide, with a maximum grade of 12 per cent. Turnouts are built every half mile. All running streams are bridged, culverts are built in dry channels, and swampy places are corduroyed, all such structures to be 12 ft. wide. The roads are carefully located with a view to future improvements.

**Road maintenance,** R. A. MEEKER (*Engin. Rec., 53 (1906), No. 13, pp. 424, 425*).—An article written for the annual report of the New Jersey commissioner of public roads. The problem of maintenance is to reduce wear and replace worn material cheaply. Good drainage is essential; the wearing surface should be hard, and should be kept free from dust by sweeping or scraping, if the rains do not keep it washed away. General repairs should be made in fall and spring, and prompt minor repairs at all seasons. The use of the best stone only is recommended.

## RURAL ECONOMICS.

**Depreciation in agricultural values,** P. CAZIOT (*Jour. Agr. Prat., n. ser., 11 (1906), No. 7, pp. 203-206*).—The value of agricultural land in France advanced during most of the nineteenth century, but since 1880 there has been a very great decrease, the decrease being as great as 70 or 80 per cent in some instances.

In general the land of the peasant proprietors has decreased to a greater extent than that of large estates. The causes given for this depreciation are that capital invested in land yields smaller returns than formerly, due to changes in agriculture which make the land a relatively less important agent in agricultural production. Intensive cultivation has given to operating capital a greater importance than it for-

merly had in agricultural operations. A second cause assigned is the decrease in rural population, which has resulted in a rise in wages.

**Report on the operation of agricultural insurance societies, A. DE CÉRIS** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 14, pp. 421, 422).—The official journal of April 1 contains a report on the operation of mutual agricultural insurance societies.

There has been in the last 9 years a very great increase in the number of these societies. There were 1,484 such societies in 1897, and 6,556 in 1906. They insure live stock against death, agricultural buildings against fire, crops against hail, and farmers against accident. The total amount of risks carried is 3,920,100 francs (about \$785,000). The government supervises the organization of the new societies, paying special attention that the rates are high enough to insure payment of indemnities. It also supervises in a limited way the operation of societies and aids them in case of special need resulting from epidemics.

The government has encouraged so far as possible the federation of the smaller societies in order that they may have greater stability.

**The loans of the Credit Foncier for agricultural enterprises, A. DE CERIS** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 14, p. 422).—The commission appointed by the ministry of agriculture to make a study of the Credit Foncier and recommend modifications to make its loans more popular, has recommended that loans for drainage and other agricultural improvement shall be made easier, that loans should be extended to agricultural societies organized under the laws of 1865-1888, that interest should be lowered, and that the system of guaranteeing reimbursement be revised.

**Meat in foreign markets, tariffs of fourteen importing nations, and countries of surplus (U. S. Dept. Agr., Bur. Statis. Bul. 39, pp. 95).**—This bulletin contains a summary of information concerning the export trade in American meat, animal and packing-house products, the customs tariffs of 14 of the principal countries importing these animals and products, and the conditions of production of these commodities for export in 12 countries which are, or may become, competitors of the United States in this industry.

**Meat animals and packing-house products imported into eleven principal countries, 1895-1904 (U. S. Dept. Agr., Bur. Statis. Bul. 40, pp. 92).**—The value of the meat animals and packing-house products imported into 13 European countries and Cuba in 1904 was \$506,715,512. Of the total amount sent to 11 of the countries included, the United States supplied 40.38 per cent.

**Norway, Sweden, and Russia as markets for packing-house products (U. S. Dept. Agr., Bur. Statis. Bul. 41, pp. 21).**—Information obtained from published official reports is summarized and classified.

The value of meat and other packing-house products imported into Norway in 1902-1904 had a value of \$4,585,000, an increase of 29 per cent over 1895-1897. In Sweden the total value of these products imported was \$4,227,000 in 1901-1903, and in Russia \$4,337,000. In Sweden the increase since 1895-1897 was 62.3 per cent. "Russia being primarily an agricultural country with an enormous export of grain, and the Russian people consuming very small quantities of meats, the imports of meat animals and packing-house products are very small and do not show any strong tendency to increase."

**Cotton production and statistics of cotton-seed products, 1905 (Bur. of the Census [U. S.] Bul. 40, pp. 72, maps 2).**—This bulletin gives cotton statistics of the United States for the years 1902, 1903, 1904, and 1905; sketches the history of the production of cotton throughout the world; discusses the possible increase of cotton growing in the United States and other countries; and describes the products made from cotton seed, giving statistics.

The total production of cotton in the United States in 500-lb. bales was 10,827,168 in 1902, 10,045,615 in 1903, 13,879,954 in 1904, and 10,804,556 in 1905. The estimated value of the cotton crop was \$501,897,134.65 in 1902, \$660,549,230.82 in 1903,

The device consists of a core 10 ft. long, with a sectional sheet-iron mold. The cement is rammed into place by hand, and the whole machine is moved gradually forward by winding up a cable by a lever and ratchet windlass. The actual cost of laying 8-in. pipe at Rochester, N. Y., was 6.6 cts. per foot, and for 12-in. pipe 10.25 cts. per foot, 300 to 400 ft. a day being laid with a crew of 7 or 8 men. While the pipes laid are said to be as tight as cement-jointed vitrified pipe, it would not be difficult to make them porous enough for drainage by using less cement or by providing openings.

**An investigation of the ancient hydraulic works in Algeria,** S. GRELL (*Paris: Govt., 1902, pp. 143, figs. 27*).—This report consists of descriptions of hydraulic works of Roman origin found in the various provinces of Algeria, written by local administrative officers, engineers, or army officers familiar with particular localities. There are described about 80 barrages, 30 reservoirs, 20 aqueducts, and a large number of smaller hydraulic works formerly used for irrigation or city water supplies.

**Strainers for driven wells,** D. H. MAURY (*Engin. News, 55 (1906), No. 10, pp. 260, 261, figs. 3*).—While fine strainers have been generally favored because they exclude fine sand, their capacity and durability are low.

The principle of the coarse strainer is that fine sand is freely admitted and may be pumped out, thus washing all the fine material from a zone surrounding the strainer and creating what is virtually a strainer of clean gravel having a large capacity, and since a certain initial velocity is required to start fine material toward the well, no silt will be drawn in when pumping any less water than the maximum capacity of the sand pump.

The author describes several well-strainers and the methods of perforating well casings after driving.

**Mountain road construction in Idaho,** F. B. DARLINGTON (*Engin. News, 55 (1906), No. 11, pp. 282, 283*).—The legislature of Idaho in 1905 authorized the expenditure of \$50,000 for mountain roads, under the supervision of a State commission, the cost of new roads to be divided with the community benefited.

Over 100 miles of road have already been built or are nearing completion under this law. It is the policy of the commission to spend only \$500 to \$1,000 per mile, the roads being 8 to 12 feet wide, with a maximum grade of 12 per cent. Turnouts are built every half mile. All running streams are bridged, culverts are built in dry channels, and swampy places are corduroyed, all such structures to be 12 ft. wide. The roads are carefully located with a view to future improvements.

**Road maintenance,** R. A. MEEKER (*Engin. Rec., 53 (1906), No. 13, pp. 424, 425*).—An article written for the annual report of the New Jersey commissioner of public roads. The problem of maintenance is to reduce wear and replace worn material cheaply. Good drainage is essential; the wearing surface should be hard, and should be kept free from dust by sweeping or scraping, if the rains do not keep it washed away. General repairs should be made in fall and spring, and prompt minor repairs at all seasons. The use of the best stone only is recommended.

## RURAL ECONOMICS.

**Depreciation in agricultural values,** P. CAZIOT (*Jour. Agr. Prat., n. ser., 11 (1906), No. 7, pp. 203-206*).—The value of agricultural land in France advanced during most of the nineteenth century, but since 1880 there has been a very great decrease, the decrease being as great as 70 or 80 per cent in some instances.

In general the land of the peasant proprietors has decreased to a greater extent than that of large estates. The causes given for this depreciation are that capital invested in land yields smaller returns than formerly, due to changes in agriculture which make the land a relatively less important agent in agricultural production. Intensive cultivation has given to operating capital a greater importance than it for-

merly had in agricultural operations. A second cause assigned is the decrease in rural population, which has resulted in a rise in wages.

**Report on the operation of agricultural insurance societies, A. DE CÉRIS** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 14, pp. 421, 422).—The official journal of April 1 contains a report on the operation of mutual agricultural insurance societies.

There has been in the last 9 years a very great increase in the number of these societies. There were 1,484 such societies in 1897, and 6,556 in 1906. They insure live stock against death, agricultural buildings against fire, crops against hail, and farmers against accident. The total amount of risks carried is 3,920,100 francs (about \$785,000). The government supervises the organization of the new societies, paying special attention that the rates are high enough to insure payment of indemnities. It also supervises in a limited way the operation of societies and aids them in case of special need resulting from epidemics.

The government has encouraged so far as possible the federation of the smaller societies in order that they may have greater stability.

**The loans of the Credit Foncier for agricultural enterprises, A. DE CERIS** (*Jour. Agr. Prat.*, n. ser., 11 (1906), No. 14, p. 422).—The commission appointed by the ministry of agriculture to make a study of the Credit Foncier and recommend modifications to make its loans more popular, has recommended that loans for drainage and other agricultural improvement shall be made easier, that loans should be extended to agricultural societies organized under the laws of 1865-1888, that interest should be lowered, and that the system of guaranteeing reimbursement be revised.

**Meat in foreign markets, tariffs of fourteen importing nations, and countries of surplus** (*U. S. Dept. Agr., Bur. Statist. Bul. 39*, pp. 95).—This bulletin contains a summary of information concerning the export trade in American meat, animal and packing-house products, the customs tariffs of 14 of the principal countries importing these animals and products, and the conditions of production of these commodities for export in 12 countries which are, or may become, competitors of the United States in this industry.

**Meat animals and packing-house products imported into eleven principal countries, 1895-1904** (*U. S. Dept. Agr., Bur. Statist. Bul. 40*, pp. 92).—The value of the meat animals and packing-house products imported into 13 European countries and Cuba in 1904 was \$506,715,512. Of the total amount sent to 11 of the countries included, the United States supplied 40.38 per cent.

**Norway, Sweden, and Russia as markets for packing-house products** (*U. S. Dept. Agr., Bur. Statist. Bul. 41*, pp. 21).—Information obtained from published official reports is summarized and classified.

The value of meat and other packing-house products imported into Norway in 1902-1904 had a value of \$4,585,000, an increase of 29 per cent over 1895-1897. In Sweden the total value of these products imported was \$4,227,000 in 1901-1903, and in Russia \$4,337,000. In Sweden the increase since 1895-1897 was 62.3 per cent. "Russia being primarily an agricultural country with an enormous export of grain, and the Russian people consuming very small quantities of meats, the imports of meat animals and packing-house products are very small and do not show any strong tendency to increase."

**Cotton production and statistics of cotton-seed products, 1905** (*Bur. of the Census [U. S.] Bul. 40*, pp. 72, maps 2).—This bulletin gives cotton statistics of the United States for the years 1902, 1903, 1904, and 1905; sketches the history of the production of cotton throughout the world; discusses the possible increase of cotton growing in the United States and other countries; and describes the products made from cotton seed, giving statistics.

The total production of cotton in the United States in 500-lb. bales was 10,827,168 in 1902, 10,045,615 in 1903, 13,679,954 in 1904, and 10,804,556 in 1905. The estimated value of the cotton crop was \$501,897,134.65 in 1902, \$660,549,230.82 in 1903,

\$652,031,635.97 in 1904, and \$632,298,322.57 in 1905. The conclusion reached regarding the production of cotton in foreign countries is that only in the remote future is there a prospect of any other country than the United States producing any large amount of cotton for export.

There has been a very large increase in the establishments making cotton-seed products since 1900, the number in that year being 369, and 715 in 1905. The value of the products increased from \$19,335,947 in 1890 to \$96,407,621 in 1905. These products include linters, hulls, and oil.

**An introduction to the history of sugar as a commodity**, ELLEN D. ELLIS (*Bryn Maur Col. Monographs*, 4 (1905), pp. 117).—This monograph presents a study of the statics and dynamics of sugar and of the history of the substance as a commodity in various countries of the world. A list of over 100 references bearing on the subject from a practical, historical, geographical, and technical standpoint is given.

### AGRICULTURAL EDUCATION.

**Higher agricultural education**, E. A. BRYAN (*Pullman, Wash.: Author*, 1905, pp. 16).—An address delivered before the Educational Congress of the Lewis and Clarke Exposition at Portland, Oreg., in which the aims of pure and applied science are set forth, and the development of agricultural education in the United States is outlined. Agricultural education is characterized as genuine, real education which can not do without the old instruments of education, but which "has added new and better instruments for the purpose of mind growth along certain directions, namely, that of the life which the student is to lead."

**Educational agriculture**, W. R. HART (*Peru, Nebr.: Author* [1906], pp. 16).—This is a discussion of the pedagogics of agriculture based on the premise that "before agriculture becomes entitled to a permanent place in the common school course it must withstand three tests: First, the test of usefulness; second, the test of mental discipline; third, the test of humanizing culture." The conclusion of the author is "that from whatever point of view the subject is approached, agriculture gives an affirmative answer to every test that can be applied to any subject, not excepting the richest, in any course of study."

**How can a college of agriculture keep close to the ground?** L. H. BAILEY (*Cornell Countryman*, 3 (1906), No. 9, pp. 207, 208).—The writer discusses means of bringing the people and the college closer together, and among other things suggests the sending of college students to approved farms to learn advanced farm practice, and the bringing of experienced farmers to the college to lecture and consult informally with students.

**Proceedings of the nineteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations held at Washington, D. C., November 14-16, 1905**, edited by A. C. TRUE, W. H. BEAL, and H. C. WHITE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 164, pp. 189, dgms. 2*).—An account of this convention has been given (*E. S. R.*, 17, p. 321).

**Proceedings of the tenth annual meeting of the American Association of Farmers' Institute Workers**, edited by W. H. BEAL, J. HAMILTON, and G. C. CREELMAN (*U. S. Dept. Agr., Office Expt. Stas. Bul. 165, pp. 95*).—This is a detailed account of the proceedings of the meeting held at Washington, D. C., November 9-11, 1905.

**Animal husbandry—four-year course**, R. S. SHAW (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 142-144).—This is a syllabus of a course in animal husbandry for graduates of a good high school, followed by a discussion of some features of the syllabus. Out of a total of 382 hours in the course 129½ hours are devoted to animal husbandry subjects, 30 hours to other agricultural subjects, and 25½ hours to hygiene, anatomy,

and veterinary science. The remainder of the time is taken up with English, mathematics, chemistry, botany, bacteriology, and drawing.

**Course in cheese making for movable schools of agriculture**, L. L. VAN SLYKE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 166, pp. 63*).—This is the first of a series of courses designed to give more extended and specific instruction in agriculture outside of regularly organized schools than is now being given in the farmers' institutes. A brief statement concerning the plan for the movable schools is given in a prefatory note by the farmers' institute specialist of this Office. The course outlined in this bulletin consists of 14 lectures accompanied by 14 practicums. The bulletin also contains a list of apparatus needed in giving the course in cheese making and lists of references to the literature of the subject.

**Syllabus for a four-year course in horticulture**, U. P. HEDRICK (*Rpt. Mich. Acad. Sci., 7 (1905), p. 141*).—This is a syllabus of a course in horticulture suitable for graduates of a good high school. Required horticultural subjects occupy 65 out of a total of 420 hours, and this number may be increased to 110 hours by choosing senior electives in horticulture.

**Teaching horticulture in high schools** (*Agriculture [Nebr.], 5 (1906), No. 2, pp. 2-6*).—Reasons for teaching horticulture and topics best suited for horticulture in high schools are given, also some items of necessary equipment, the most important of which is the school garden.

**Topics in horticulture for common schools**, U. P. HEDRICK (*Rpt. Mich. Acad. Sci., 7 (1905), p. 140*).—Horticultural topics suitable for common schools are arranged under the three heads propagation of plants, vegetable gardening, and pomology.

**Outline for a brief course in agricultural economics**, K. L. BUTTERFIELD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 149, 150*).

**Outline for a brief course in rural sociology**, K. L. BUTTERFIELD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 150, 151*).

**Courses in some phases of rural economy. Outline for a course in farm management**, F. W. CARD (*Rpt. Mich. Acad. Sci., 7 (1905), pp. 148, 149*).

**Teaching agricultural economics in the agricultural high schools**, E. VLIEBERGH (*Rev. Gén. Agron., 14 (1905), Nos. 10-11, pp. 444-452*).—The author states that agricultural economics might be held to include studies of agricultural practice and also studies of economic, social, political, and legal conditions, but confines his discussion to the latter. A complete course of instruction is outlined. It includes property rights in land; rents; statistics; land taxes; tariff; public regulations; size of land holdings; succession; subdivision of holdings; credit; capital; labor; insurance; agricultural associations; teaching of agriculture; sanitary regulations, etc. It is recommended that class work be supplemented by the preparation of monographs, students studying conditions in their home communities and by seminar work.

**How to determine what to teach in nature study**, L. A. HATCH (*Nature-Study Rev., 2 (1906), No. 1, pp. 13-17*).—An argument in favor of teaching nature study with a clearly defined object in view. The writer holds that in planning a course in nature study "(1) A vital human relation should be found in all the work undertaken; (2) the course should contain within itself a rich content that is worth studying; (3) there should exist an intimate relation among the parts, holding the same together in such a manner that the work covered from year to year will be progressive and united."

**Nature study in its practical bearings**, J. P. STEWART (*Nature-Study Rev., 2 (1906), No. 2, pp. 55-66; reprinted from [Ill.] Normal School Quart.*).—A discussion of the reason for teaching nature study, its relation to agricultural teaching, what it should include, the principles that should guide in its organization and presentation, and the place where it should be taught. The writer's answer to the last question is "The all-important place for nature study is in the country school." The two prob-

lems for discussion in reaching the country school are (1) how to reach the teacher and (2) what to do in these schools, and how.

**The relation of nature study to manual training**, W. A. BALDWIN (*Nature-Study Rev.*, 2 (1906), No. 2, pp. 41-48, figs. 2).—The writer discusses the relationships between these two subjects from 2 standpoints, that of the subject taught and that of the child. In the first case he shows that while nature study and manual training were once wide apart, they have been modified until they come very near together. Secondly, from the standpoint of the child, "the only true line of approach," he finds that it is difficult to distinguish between the two—that with the child at home on the farm most of nature study is also manual training, and vice versa.

**Experiences in school gardening**, J. B. DANDENO (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 156-160).—An argument against the feasibility and desirability of conducting school gardens in rural schools based on the experience of the writer in growing plants and trees in a country school, and against teaching elementary agriculture in such schools based on the premise that "agriculture is purely and necessarily an art," and that in order to teach it the sciences botany, zoology, chemistry, physics, mineralogy, and geology would have to be taught.

**The school garden at Bowesville, Canada**, E. A. HOWES (*Nature-Study Rev.*, 2 (1906), No. 2, pp. 48-55, figs. 2, dgm. 1).—An interesting account is given of a successful experiment "to determine what might be accomplished along the line of nature study by means of a school garden in a large ungraded rural school, under stable conditions, by a trained teacher supposed to be interested in the work." While the work in the lower grades did not differ materially from other school garden work, that in the upper grade consisted largely of cultural and spraying experiments with potatoes, this crop being one of the leading staples of the region.

**The preparation of teachers for the rural common schools**, E. BURNHAM (*Rpt. Mich. Acad. Sci.*, 7 (1905), pp. 152-155).—After discussing some of the essentials of training for rural school teachers, the author considers the county normal training classes now in vogue in Michigan and the courses for rural teachers in the State normal schools.

**The school garden and the country school**, G. D. FULLER (*Ottawa Nat.*, 19 (1906), No. 12, p. 235-246, dgm. 1).—An account of school garden work in connection with a Macdonald rural school at Brome, Quebec, giving particulars regarding the conduct of the garden work during the winter and spring terms, and in the summer vacation.

**True nature study: Its fundamentals and its relation to some other subjects**, J. V. CRONE (*Nature-Study Rev.*, 2 (1906), No. 5, pp. 177-184).

**Nature study and gardening**, ESTELLE REEL (*Washington: Govt. Printing Office*, 1905, pp. 27, figs. 4).—A bulletin giving suggestions to teachers in Indian schools regarding nature study lessons, window boxes, and gardening.

**Education in Indian rural schools. A plea for nature study**, F. G. SLY (*Agr. Jour. India*, 1 (1906), No. 2, pp. 115-122).—An argument for rural school instruction dealing with concrete objects before abstract, proceeding from the known to the unknown, and basing instruction upon the familiar surroundings of the child.

"The familiar surroundings of the rural school boy are essentially agricultural, so that his education should very largely be based upon agriculture." A distinction is made between teaching agriculture, which is not recommended, and teaching nature study through the use of agricultural material, which is strongly urged. Suggestions are given for training teachers in cooperation between the education and agricultural departments of India.

**Royal Hungarian Central Viticultural Institute** (*L'Institut Central Ampelologique Royal Hongrois. Budapest, 1905, pp. 15, figs. 6, dgm. 2*).—This is a description of the organization, buildings, and other equipment of the Royal Hungarian Central Viticultural Institute opened at Budapest in 1904. The institute includes divisions of

biology, chemistry, zymology, and viticulture and enology, each under a chief subordinate to the director of the institute. The buildings include a main building containing offices, library, museum, auditorium, lecture rooms, and laboratories, and 4 separate laboratory buildings, one for each division. In the vicinity of the buildings are several vineyards containing American and European vines and hybrids.

**Agricultural education in India**, J. HARWARD (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 25 (1905), No. 5, pp. 717-722).—An historical and general account of agricultural education in India, including the work done in agricultural colleges, secondary schools, and rural schools

**Schools for colonial agriculture**, REINECKE (*Tropenpflanzer*, 10 (1906), No. 4, pp. 238-243).—An account is given of the schools for colonial agriculture existing in the different countries of Europe and European colonies.

## MISCELLANEOUS.

**Fourteenth Annual Report of Colorado Station, 1901** (*Colorado Sta. Rpt. 1901*, pp. 53).—This report, recently issued, contains a financial statement for the fiscal year ended June 30, 1901, and reports of the director, heads of departments, and field agents of the station, parts of which are abstracted elsewhere in this issue. The report of the Plains Substation includes notes on weather conditions, various horticultural and field crops grown during the year, stock raising, irrigation, and other topics.

**Report of Florida Station, 1903** (*Florida Sta. Rpt. 1903*, pp. 19).—This contains a report of the director, a financial statement for the fiscal years ended June 30, 1902-3, a list of the bulletins issued by the station, and brief reports of the heads of departments.

**Report of Florida Station, 1904** (*Florida Sta. Rpt. 1904*, pp. 22).—This contains a report of the director, a financial statement for the fiscal year ended June 30, 1904, departmental reports, and a list of the publications of the station available for distribution.

**Seventeenth Annual Report of Illinois Station, 1904** (*Illinois Sta. Rpt. 1904*, pp. 13).—This contains a brief statement concerning the principal lines of station work during 1904, a list of the bulletins published by the station, and a financial statement for the fiscal year ended June 30, 1904.

**Twentieth Annual Report of Maine Station, 1904** (*Maine Sta. Rpt. 1904*, pp. 226).—This is made up entirely of reprints of Bulletins 100-111 of the station which were issued during the year.

**Twenty-first Annual Report of Maine Station, 1905** (*Maine Sta. Rpt. 1905*, pp. 268).—This is made up entirely of reprints of Bulletins 112-124 which were issued during the year.

**Fourteenth Annual Report of New Mexico Station, 1903** (*New Mexico Sta. Rpt. 1903*, pp. 30).—This contains a report of the director on the work of the station during the year with a list of press bulletins issued, periodicals received by the station, and a list of the available bulletins and reports to date. Departmental reports containing in some instances experimental work are included and a financial statement is given for the fiscal year ended June 30, 1903.

**Twenty-third Annual Report of the New York State Station, 1904** (*New York State Sta. Rpt. 1904*, pp. 457).—This contains a financial statement for the year ended September 30, 1904, a list of periodicals received by the station, meteorological observations noted elsewhere, and reprints of Bulletins 245-260 of the station.

**Ohio Agricultural Experiment Station** (*Ohio Sta. Circ. 48*, pp. 3).—This calls attention to the nature and results of the work of the station as a justification for asking for an increase in the State appropriation.

**Fifteenth Annual Report of Wyoming Station, 1905** (*Wyoming Sta. Rpt. 1905, pp. 77*).—This includes the organization list, a report of the director on the work and publications of the station during the year, a financial statement for the fiscal year ended June 30, 1905, and reports of the heads of departments, parts of which are noted elsewhere. The director's report contains also statements concerning recent State legislation of interest to the station.

A report on lamb feeding experiments has been noted from another publication (*E. S. R.*, 17, p. 688). Analyses of forage plants are reprinted from Bulletin 65 of the station (*E. S. R.*, 17, p. 240).

**Report of the Secretary of Agriculture, 1905**, JAMES WILSON (*U. S. Dept. Agr., Rpt. 81, pp. 100*).—This is a separate of the Secretary's report previously noted (*E. S. R.*, 17, p. 923).

**Publications of the Office of Experiment Stations issued during 1905 and station publications received by the Office of Experiment Stations during 1905** (*U. S. Dept. Agr., Office Expt. Stas. Circ. 66, pp. 14*).—Previous lists of this kind have been published in the bulletins and annual reports of this Office, and recently reprinted and distributed in the form of separates, which with the present circular furnishes a complete list of all the publications of this Office and the experiment stations since their organization up to the end of 1905.

**Accessions to the Department Library, 1906** (*U. S. Dept. Agr., Library Bul. 59, pp. 77*).

## NOTES.

---

**Alabama College and Station.**—W. T. Clarke, assistant superintendent of university extension and assistant in entomology of the California University and Station, has been appointed entomologist of the station. W. Gilder, a graduate of the veterinary college of Cornell University, has been appointed assistant in veterinary science, vice I. S. McAdory, resigned. D. T. Gray has been promoted to assistant professor of animal industry. E. R. Miller, formerly in charge of the department of pharmacy and recently connected with the Cuban experiment station, has been elected professor of pharmaceutical chemistry, vice W. H. Blome, resigned to engage in commercial pursuits.

**Connecticut State Station.**—The station entomologist is devoting his attention to the gypsy moth, which has made its appearance in the State. One square mile of territory near Stonington is said to have been invaded.

**Georgia College.**—The State legislature has appropriated \$100,000 for the purpose of erecting and equipping buildings for the agricultural college. Through the efforts of the alumni of the institution, the university has recently acquired 500 acres of land adjoining the campus.

**Illinois University and Station.**—W. C. Coffey has been appointed instructor in sheep husbandry and D. O. Barto instructor in agriculture. Mr. Barto will make a study of those phases of agriculture suitable for use in secondary schools. The following additions have been made to the station staff: L. Hagenaur and A. F. Kidder, department of agronomy; H. O. Allison, department of animal husbandry; and J. M. Barnhart, department of dairy husbandry.

**Kentucky Station.**—George Roberts has been appointed assistant chemist.

**Maryland Station.**—C. W. Melick, assistant in dairy husbandry at the Kansas Agricultural College, has been appointed dairyman of the station to take effect September 1. H. Jennings, a graduate of Cornell University, in the class of 1906, has been appointed poultryman to take effect September 1. E. H. Brinkley, formerly of the station, has been appointed assistant in demonstration work to take effect October 1. The last two positions have been provided for by station appropriations.

**Massachusetts Station.**—L. S. Walker was appointed assistant chemist in the division of foods and feeding July 1, vice A. C. Whittier, resigned.

**New Hampshire College.**—Dr. T. J. Headlee has been appointed entomologist and F. W. Putnam assistant professor of drawing.

**Cornell University.**—Dr. T. L. Lyon, recently appointed professor of experimental agronomy in the college of agriculture, will devote his time to research, taking up his work about September 1. Dr. G. F. Warren, horticulturist of the New Jersey Station, has been appointed assistant professor of agronomy. E. O. Fippin, heretofore detailed by the Bureau of Soils of this Department, will remain with the university as assistant professor of agronomy with reference to soils. J. W. Gilmore, instructor in agronomy, has been made assistant professor of agronomy. The college of agriculture now has six professors in agronomy. C. F. Clark has been appointed assistant agronomist.

**New York State Station.**—Director W. H. Jordan has been granted a four months' leave of absence, the first half of which he will spend in the West. E. B. Hart, associate chemist, has resigned to accept the position of professor of agricultural chemistry in the University of Wisconsin, and chemist of the experiment station. Increased appropriations for the next fiscal year have permitted the following promotions and additions to the station staff: W. J. Schoene, assistant entomologist; James Wilson, of the Oklahoma Agricultural College, assistant bacteriologist; Richard Wellington, of the Massachusetts Agricultural College, assistant horticulturist; and G. T. French, of the Massachusetts Agricultural College, assistant botanist.

**Ohio Station.**—Edmund Secrest, a graduate of the Kansas Agricultural College and recently connected with the Forest Service of this Department, has been appointed assistant in forestry at the station.

**Oklahoma Station.**—W. L. English, a graduate of the Oklahoma Agricultural and Mechanical College, for some time assistant in animal husbandry in the college and station, and at present engaged in farming in Pottawatomie County, Okla., has been appointed director of the Oklahoma Agricultural Experiment Station, and will assume the duties of the position September 1, 1906.

**Rhode Island College and Station.**—Dr. Cooper Curtice has resigned to take up work in the Bureau of Animal Industry of this Department in connection with the eradication of the Texas fever tick. J. G. Halpin, instructor in poultry husbandry in the college, has resigned to accept a similar position in the Michigan Agricultural College. J. W. Bolte, a graduate of the Michigan Agricultural College and poultryman of the Utah College and Station, has been appointed assistant professor of animal industry and will have charge of poultry instruction. He will also be connected with the experiment station. Prof. F. C. Black, of the Indiana Normal University and College of Applied Science, has been appointed to the chair of highway engineering and will begin his new duties in September.

**Tennessee Station.**—S. E. Barnes, dairyman of the station, has been engaged by the dairy division of the Bureau of Animal Industry to do field work in Tennessee in the interests of dairying, in which work he will cooperate with the station. The vacancy has been filled by the appointment of J. N. Price. L. R. Neel has been appointed assistant in plat work, vice J. E. Converse, resigned to become manager of a farm in the vicinity of Knoxville.

**Utah Station.**—James Dryden, formerly connected with the station and more recently poultryman of the Montana Station and at present with the Cyphers Incubator Company, of Buffalo, N. Y., has been appointed poultryman, vice J. W. Bolte, resigned. C. Larsen, assistant in dairying at the Iowa College and Station, has been appointed dairyman to fill the vacancy caused by the resignation of J. A. Crockett, who will engage in private business.

**Virginia College and Station.**—Prof. R. J. Davidson, dean of the scientific department and chemist of the station, has severed his relations with the station in order to devote his entire time to the scientific department. The vacancy on the station staff has been filled by the appointment of Dr. W. B. Ellett, assistant chemist of the station. It is planned to reorganize the department with a first assistant and one or two laboratory assistants and to undertake new lines of investigation made possible by the Adams Act. W. L. Owen, recently appointed to take charge of the cooperative investigations in light tobacco at Chatham, Va., has resigned to accept a position in bacteriology in the Georgia Station. The vacancy has been filled by the appointment of R. P. Cocke. The State farmer's institute recently held at Roanoke was attended by 1,200 farmers, of whom 1,050 visited the college and station on a special train provided for their accommodation.

**Bequest to the University of California.**—The estate of the late M. Theodore Kearney, near Fresno, comprising about 5,000 acres of land, valued at nearly \$1,000,000 and yielding an annual income of about \$50,000, has been bequeathed to the University

of California, preferably for endowment of agricultural education and research. President Wheeler has expressed his belief that the trustees of the university will assume the responsibilities involved in accepting this trust.

**International Congress of Agriculture.**—The Eighth International Congress of Agriculture will be held at Vienna, Austria, May 21–25, 1907. The previous Congresses were held at Paris, 1889; The Hague, 1891; Brussels, 1895; Budapest, 1896; Lausanne, 1898; Paris, 1900, and Rome, 1903. A pamphlet has been issued giving the organization, regulations, and programme of the forthcoming congress. This contains the subjects for discussion of each of the eleven sections in which the congress is to be divided. All reports intended for the congress should be sent to the executive committee before December 1, 1906. Persons desirous of becoming members should notify the executive committee and pay the membership fee of 20 kronen (§4) before March 31, 1907. The secretary of the executive committee is Prof. Josef Hausler, Vienna, Austria, I. Schauffergasse 6.

**Indian forestry college.**—In order to make better provisions for research work in forestry, and to secure a permanent staff of forest experts for scientific research, as well as for training candidates for the government and state forestry service, the Imperial Forestry School at Dehra Dun, India, has been enlarged and hereafter will be known as the Imperial Forestry Research Institute and College. The college staff will include officers of the imperial service, holding the following positions: (1) Sylviculturist, who will make sylviculture his special study. (2) Superintendent of Forest Working Plans, who will collect and collate statistics of the results of forestry management throughout India. (3) Forest Zoologist, who will investigate the damages caused by insects and other pests. (4) Forest Botanist, who will study the botany of forest plants, distribution of species, diseases of forest trees, etc. (5) Forest Chemist, who will investigate the chemical properties of soils and forest produce. (6) Forest Economist, who will study economic methods of commercial timber production and marketing.

These officers, while engaged primarily in research work, will each deliver a course of lectures on his special subject in the college, and take part in the training of the students. The work of instruction, however, will for the most part be carried on by four assistant instructors.

**Miscellaneous.**—*Science Progress*, published in London from 1894 to 1898, has been revived under the name *Science Progress in the Twentieth Century*. The journal is to be issued quarterly. The first number contains, among others, articles on The Solvent Action of Roots upon the Soil Particles, by A. D. Hall, On the Occurrence of Prussic Acid and its Derivatives in Plants, by T. A. Henry; Some Notable Instances of the Distribution of Injurious Insects by Artificial Means, by F. V. Theobald; The Corn Smuts and their Propagation, by T. Johnson; and the Utilization of Proteids in the Animal, by F. G. Hopkins.

J. B. Mowry has been appointed commissioner of forestry in Rhode Island.

William Farrer, wheat specialist to the department of agriculture of New South Wales, died April 17, 1906. Mr. Farrer was noted especially for his work in the improvement of wheat by cross-breeding and selection, particularly in the direction of producing types resistant to rust and drought.

Prof. Gustav W. Lehman, prominent as a food chemist, died in Baltimore, August 5, 1906.

Dr. George W. Atherton, president of The Pennsylvania State College, died at that place July 24, 1906.

Last autumn, in the hope that a milder climate might be helpful, he went to southern California, where he spent the winter. Although the change for a time seemed beneficial, yet the relief proved to be but temporary. Upon his return home he gradually grew weaker until his disease culminated in death. At the last commencement, although extremely weak, he expressed a desire to meet the graduating

class and confer the degrees. This was his last public service to the institution over which he had presided for 24 years.

During his presidency the college developed from an institution with a small number of students, few buildings, and an inadequate teaching force to its present large attendance, ample equipment, and high position as an educational institution. Much of this progress was due to Doctor Atherton's indefatigable energy and intelligent interest in the development of technical education.

Doctor Atherton was born in Boxford, Mass., June 20, 1837. At the age of 12 his father died, leaving him with his mother and sister only partially provided for. His first employment was in a cotton mill, and later upon a farm. He worked his way through Philips Exeter Academy and Yale College, being graduated from the latter institution in 1863. He served in the civil war from 1861-63 as lieutenant and captain in the Tenth Connecticut Volunteers; was a teacher in the Albany Boys' Academy, 1863-67; professor in St. John's College, Annapolis, Md., 1867-68, and in the University of Illinois, 1868-69; was professor of political economy in Rutgers College, New Jersey, 1869-82; and president of The Pennsylvania State College, 1882-1906. The degree of LL.D. was conferred upon him by Franklin and Marshall College in 1883. He was one of the original organizers of the Association of American Agricultural Colleges and Experiment Stations, and was the first president of the organization.

# INDEX OF SUBJECTS.

NOTE.—The abbreviations "Ala. College," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective experiment stations; "Alaska," "Hawaii," and "P. R." to those of the experiment stations in Alaska, Hawaii, and Porto Rico; "Can." to those of the experiment stations in Canada, and "U. S. D. A." to those of this Department.

	Page.		Page.
Abattoir. ( <i>See</i> Slaughterhouse.)		African coast fever, control	404, 500, 912
<i>Abies pectinata</i> as affected by origin of seed.	668	immunity to	265
Abortion, contagious	908, 909, 1191	notes	266, 404, 591, 592, 804
control	1011	transmission	189
in cows	701, 807, 912, 1015	treatment	295
sheep and goats	406	wonder grass, analyses	1178
discussion, U. S. D. A.	190	<i>Agamopsycha threnodes</i> , notes, Hawaii	477
due to tuberculosis	404	Agar-agar, carbohydrates of	889
noncontagious	701, 807, 1015	Agathi plant, notes	755
treatment	590	Agave disease, notes	375
Abscesses in cattle, bacteria in	592	Agglutination in glands	809
<i>Acacia farnesiana</i> , analyses, Hawaii	1177	Agglutinins in glands	808
<i>pendula</i> , notes	256	milk	76
Acarina, treatise	882	Aggressins, immunization with	805
<i>Acer pseudoplatanus</i> , seed selection	668	Agricultural—	
Acetamid, determination	428	charts	537
Acid phosphate. ( <i>See</i> Superphosphate.)		chemical station at Vienna	98, 821
<i>Acidia heraclei</i> , notes	676	chemistry, reviews	10
Acidimetry, sodium carbonate and oxalate		clubs for boys, U. S. D. A.	198
in	10	college at Cirencester	414
Acids, free, determination in superphosphates	7, 936	East of Scotland	309, 927
organic, effect on phosphates	449	farm, purpose	216
in wines	439	Cal	1022
<i>Acridium purpuriferum</i> , notes	989	for girls	197
<i>Acrobasis nebulosa</i> , notes, Fla.	479	in Manitoba	202
Actinobacillosis, notes	401, 1188	Nova Scotia	309
Actinobacillus, studies	292	colleges, attendance at	202
Actinomyces, classification	1013	courses in	326
notes	500	duties and responsibilities of	321
studies	292	exhibit at live-stock exposition	420
Actinomycoosis, forms	292	St. Louis	324
notes	401	extension work by	96, 305, 410, 818
pathology	913	field and functions	326
prevalence in Massachusetts	1011	for negroes	922
Ohio	804, 1189	in the South	713
Adams Act, editorial note	725	laws concerning	96
County, Pa., soil survey, U. S. D. A.	740	management	1198
H. C., biographical sketch	1029	military instruction in	322
<i>Adoretus umbrosus</i> , notes, Hawaii	785	organization lists, U. S. D. A.	715
Aerial research, international conference, U. S. D. A.	10	relation to farmers	328
Aeronautical observatory at Lindenberg, U. S. D. A.	735	State universities	328
Aeronautics, scientific, U. S. D. A.	637	statistics, U. S. D. A.	922
Aero-physical observatory in Japan, U. S. D. A.	1042	student control	327
		( <i>See also</i> Alabama, Arizona, etc.)	
		colonies, report on	816
		conditions in Argentina	11
		Washington	91
